7. The beginning of the proof. The following theorems are true:

**Theorem 7.1.** Let $\mathcal{T}$ be a $t$-category. Let $\mathcal{C}$ be its heart. Then the inclusion

$$
\mathcal{C} \to \mathcal{T}_{[0,0]}
$$

induces a homotopy equivalence.

**Theorem 4.8.** Let $\mathcal{A}$ be an abelian category. The natural inclusion

$$
\mathcal{A} \to \text{Gr}_{[0,0]}(\mathcal{A}) \to \text{Gr}^b(\mathcal{A})
$$

induces a homotopy equivalence.

In this article, we will give a complete proof of Theorem 4.8. In *K-theory for triangulated categories II* we will prove Theorem 7.1, in the special case $\mathcal{T} = D^b(\mathcal{A})$ with the usual $t$-structure. The general proof of Theorem 7.1 will have to wait until *K-theory for triangulated categories III*. Conceptually, the general proof of Theorem 7.1 is no harder; but the details are complicated. The proof involves many more homotopies, hence we leave it for a subsequent article.

The proof given for Theorem 7.1 (in the special case) will also provide a proof for Theorem 4.8. But first we will present another, simpler proof of Theorem 4.8. The simpler proof has two virtues. Firstly, it is simpler. Secondly, all but the very last step works for Construction 4.6, and the last step pinpoints just where we need the coherent choice of differentials. This second point is important. Because most of the proof is valid for Construction 4.6, we will be able to make certain deductions about the homotopy type of that construction.

The proofs of our two theorems begin the same way. In this section we will give the common beginning. Everything in this section is valid for all four constructions.

*Beginning of the Proof.* Because $\mathcal{T}^b = \bigcup_{m \leq n} \mathcal{T}_{[m,n]}$, it will suffice to show that for $m' \leq m \leq n \leq n'$, the inclusion $\mathcal{T}_{[m,n]} \subset \mathcal{T}_{[m',n']}$ induces a homotopy equivalence on whichever construction we work with. Clearly, it suffices to consider two cases:

7.1.1. $m' = m - 1$, $n' = n$;
7.1.2. $m' = m$, $n' = n + 1$.
These cases being dual, we will only consider 7.1.1. For convenience of notation, we will prove that $T_{[1,n]} \subset T_{[0,n]}$ induces a homotopy equivalence.

**Notation 7.2.** An arrow $\rightarrow$ is a “monoepi”; it stands for a morphism which is at once a mono and an epi. Such a morphism is mono in degree 0, epi in degree $n$. There is now an obvious way to define yet more simplicial sets. The symbol stands, of course, for the nerve of the bicategory which is horizontally free and vertically monoepi. We can also define simplicial sets with coherent differentials, where some of the arrows are constrained to be monoepi.

**Motivation for the Remainder of Section 7.** Before we go on to more detail of the proof, it would perhaps be helpful to summarize briefly what we will do in the remainder of this section. The remainder of this section consists of a string of lemmas, that identify the homotopy fiber of the map

$$Gr_{[1,n]} \rightarrow Gr_{[0,n]}.$$ 

More precisely, we will show that the map

$$Gr_{[0,n]} \rightarrow Gr_{[1,n]}$$ 

is a quasi-fibration, and the simplicial set on the left is a model for

$$Gr_{[1,n]}$$

while the simplicial set on the right is clearly a model for
After all, whatever the simplicial set on the left happens to be, by the time we cross out enough to obtain the simplicial set on the right, all we are left with is

\[
\begin{array}{c}
\uparrow \\
Gr_{[0,n]}
\end{array}
\]

together with some cokernels.

This is true in both Constructions 4.6 and 4.7, i.e. with or without differentials, but only for \( Gr(\mathcal{A}) \). If we want a theorem about the \( K \)-theory of a triangulated category \( \mathcal{T} \), we run into problems already at this early stage.

We will not identify the homotopy fiber of

\[
\begin{array}{ccc}
\uparrow & & \\
\mathcal{T}_{[1,n]} & \hookrightarrow & \mathcal{T}_{[0,n]}
\end{array}
\]

We will not quite succeed in proving that the map

is a quasifibration (at least, in this section we will not succeed. Ultimately we will, of course, even show that the fibers are contractible.) Instead, we will show here that the fiber over the trivial simplex 0 controls the situation. The fiber over a general simplex \( X \) is the simplicial set
The fiber over 0 is obtained by setting the entire box labeled $X$ to be 0; it is the simplicial set which we will denote

What we will show is that, if the fiber over 0 is contractible, all the other fibers must also be. Thus to prove Theorems 4.8 and 7.1, it suffices to show that the fiber over 0 is contractible.

From now on, we will begin committing the notational crime of letting $\mathcal{T}$ stand for either a triangulated category $\mathcal{T}$, or $Gr(\mathcal{A})$. Thus

<table>
<thead>
<tr>
<th>$\mathcal{T}$</th>
<th>$\mathcal{T}_{[0,n]}$</th>
</tr>
</thead>
</table>

can either be the $K$–theory of a triangulated category, or the $K$–theory of $Gr(\mathcal{A})$ for some abelian category $\mathcal{A}$. It can, unless further specified, come either with or without coherent differentials.

**End of Motivation.**

We break the proof into steps.

**Lemma 7.3.** The natural inclusion

$$
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \\
\mathcal{T}_{[1,n]} \\
\mathcal{T}_{[0,n]}
\end{array}
\end{array}
\end{array}
$$

$$
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \\
\mathcal{T}_{[0,n]}
\end{array}
\end{array}
\end{array}
$$
induces a homotopy equivalence.

Proof. Consider the trisimplicial set together with the two projections

\[ \begin{array}{c}
0 \\
\downarrow \\
0 \\
\downarrow \\
0 \\
\downarrow \\
0
\end{array} \]

\[ \begin{array}{ccc}
\mathcal{T}_{[1,n]} & \to & \mathcal{T}_{[0,n]} \\
\downarrow & & \downarrow \\
\mathcal{T}_{[1,n]} & \to & \mathcal{T}_{[0,n]}
\end{array} \]

\[ \begin{array}{cc}
f_1 & \\
\wedge & \\
f_2 & \\
\wedge & \\
\wedge & \\
\wedge & \\
0
\end{array} \]

Notation 7.4. The simplicial set
is just

In other words, the zero inside a rectangle means simply that the restrictions on the objects and morphisms can be deduced from the surrounding data, and the author is too lazy to do it explicitly.

To prove that $f_1$ is a homotopy equivalence, it suffices to establish the contractibility of
This is easily done, with the contracting homotopy.

To prove that \( f_2 \) is a homotopy equivalence, it suffices to establish the contractibility of
This is also easily done, with the contracting homotopy

In other words, both simplicial sets are contractible by the “contraction to the initial object”. The reader should reflect a little to see that neither homotopy wanders outside its simplicial set. This is slightly tricky in the case of $f_2$. The real point is that, if $Y_{ik} \overrightarrow{\leftrightarrow} Y_{jk}$ is a monoepi in $T_{[0,n]}$, and we complete it to a triangle

\[
\begin{array}{c}
Z_{ji} \overrightarrow{\leftrightarrow} Y_{ik} \overrightarrow{\leftrightarrow} Y_{jk} \overrightarrow{\leftrightarrow} \Sigma Z_{ji},
\end{array}
\]

then $Z_{ji}$ is in fact an object of $T_{[1,n]}$. This follows immediately from the long exact homology sequence. \qed

\textbf{Strategy of the remainder of the Section.} We study the projections
In Lemma 7.5 we will show that $f_1$ is a homotopy equivalence. In Lemmas 7.6, 7.11 and 7.15 we will show that $f_2$ is (almost) a quasi-fibration. In particular, to prove it a homotopy equivalence, it suffices to establish the fiber over 0 contractible.

End of Strategic Planning.

**Lemma 7.5.** The map $f_1$, above, that is
induces a homotopy equivalence.

Proof. It suffices, by Segal’s theorem, to show that the fiber

is contractible; and this is immediate from the contracting homotopy
Lemma 7.6. Suppose $\mathcal{T}$ is either $D^b(A)$ with the standard $t$-structure, or $G^b_t(A)$. Let $f_2$ be the map

Then the fiber of $f_2$ in the sense of Segal, i.e. the simplicial set
is homotopy equivalent to a much smaller-looking simplicial set. Precisely, if the fixed data $X$ is given by the diagram

$$
\begin{array}{ccc}
X_{p0} & \cdots & X_{pq} \\
\uparrow & & \uparrow \\
\vdots & & \vdots \\
X_{00} & \cdots & X_{0q}
\end{array}
$$

then the fiber $f_2^{-1}(X)$ is homotopy equivalent to the simplicial set we will denote

$$
\begin{array}{ccc}
0 & & \\
\uparrow & & \uparrow \\
\vdots & & \\
X_{[0,n]} & & \\
\uparrow & & \uparrow \\
H^0(X_{p0}) & & 
\end{array}
$$

In particular, its homotopy type depends only on $X_{p0}$, and not on the entire simplex $X$. The symbol $H^0(X_{p0})$ stands for $X_{p0}^{\leq 0} = X_{p0}^{\leq 1}$. It is the bottom homology of $X_{p0}$, placed in degree 0. From now on we will denote it $X_{p0}^{\leq 1}$, as this is the easiest on the eye, having the fewest sub- and superscripts.

**Notation 7.7.** The object $X_{p0}$ plays a crucial role in many homotopies. We will refer to it as $X_{NW}$. The notation means that we pick the North–West corner of the simplex $X$. We can, of course, also refer to $X_{NE}$, $X_{SW}$ and $X_{SE}$. Naturally enough, these stand for the North–East, South–West and South–East corners of $X$ respectively. But it turns out that of these $X_{NW}$ and $X_{SE}$ play a disproportionately important role. Of course, $X_{NW}$ and $X_{SE}$ are permuted by the duality and transposition symmetries. If one plays a major role, so must the other.
Proof of Lemma 7.6. Once again, the idea is to use our favorite homotopy. The fiber in the sense of Segal is the simplicial set

\[
\begin{array}{c}
\downarrow \quad \downarrow \\
S \\
\downarrow \quad \downarrow \\
0 \\
\downarrow \quad \downarrow \\
\tau_{[0, n]}[\cdot] \\
\downarrow \quad \downarrow \\
X
\end{array}
\]

To this fiber we will apply a homotopy we will denote

\[
\begin{array}{c}
\downarrow \quad \downarrow \\
S \\
\downarrow \quad \downarrow \\
0 \\
\downarrow \quad \downarrow \\
\tau_{[0, n]}[\cdot] \\
\downarrow \quad \downarrow \\
/ X^<1_{NW} \\
\downarrow \quad \downarrow \\
X
\end{array}
\]

and as the notation is meant to suggest, the homotopy is a slight variation on our old friend. Now we need to explicitly describe the homotopy.

An \( n \)-simplex \( s_n \) in the fiber is a diagram of \( M - V \) squares
and to define a homotopy, we need to associate to it \( n + 1 \) \((n + 1)\)-simplices. The \( i^{th} \) is given by the now familiar looking diagram.
The reader should note that this is really nearly the same as the homotopy in the
proof of Theorem 5.1. If the reader quickly refers back to the diagram defining the
homotopy **, he will observe it to be identical with the above, except for the triangle
of S's at the top (which is harmless), and for the fact that in the rectangle surrounded
by dashes, every term has been divided by \( X_{NW}^{<1} = X_{p0}^{1} \). Now we will explain what
this means.

The point is that, in a triangulated category with a t-structure, there is a func-
torial way to divide an object \( X \in \mathcal{T}^{\geq 0} \) by a subobject \( A \in \mathcal{T}_{[0,0]} \). Precisely, this means
that if \( A \in \mathcal{T}_{[0,0]} \) and \( X \in \mathcal{T}^{\geq 0} \) are given, together with a mono (in the exact category
\( \mathcal{T}^{\geq 0} \), where they both lie) \( f : A \to X \), then one can form the quotient \( \frac{X}{A} \), which
is unique up to canonical isomorphism. In the above, put \( A = X_{NW}^{<1} \). The objects
\( Z_{jk} \) lie in \( \mathcal{T}^{\geq 1} \), and hence the only map \( A \to Z_{jk} \) is the zero map. But there is a
canonical inclusion \( A \hookrightarrow X_{NW} \), and hence a canonical map \( A \hookrightarrow Z_{jk} \oplus X_{NW} \). The
map \( A \leftrightarrow Y_{0k} \oplus X_{NW} \) is defined simply to be the composite

\[
A \leftrightarrow Z_{jk} \oplus X_{NW} \leftrightarrow Y_{0k} \oplus X_{NW}.
\]

The highlighted box in the simplex above contains the quotients by this inclusion of
\( A \).

**Caution 7.8.** The reader should note that it is not entirely trivial that all the
squares in the diagram above give rise to distinguished triangles. Modulo difficulties
with mapping cones on triangles, it is nevertheless true. We will come back to this
point in Sections II.1 and III.1, where we will give a more general discussion of why
the variants of our favorite homotopy are all well defined.

The proof that the various squares are \( M - V \) can wait until Sections II.1 and
III.1, but what cannot wait is a computation of the map

\[
Z_{jk} \oplus X_{NW} \leftrightarrow Y_{0k} \oplus X_{NW}.
\]

Trivial as the computation is, it is so important that I will label it a proposition.

**Proposition 7.9.** In the simplex above, which is part of the definition of our
favorite homotopy, the map

\[
Z_{jk} \oplus X_{NW} \leftrightarrow Y_{0k} \oplus X_{NW}
\]

is the matrix

\[
\begin{pmatrix}
\alpha & -\beta \\
0 & 1
\end{pmatrix}
\]

where \( \alpha : Z_{jk} \to Y_{0k} \) and \( \beta : X_{NW} \to Y_{0k} \) are the natural structural morphisms of
the simplex \( s_n \).

**Proof.** There are several ways to prove this. We will indicate three, and leave the
details as an exercise to the reader.

The first way is to remember that the distinguished triangles in the homotopy **
were defined in terms of direct summands on mapping cones of triangles. These were
all very explicit, so we can now get in and compute.
The second way is to remember the metatheorem which tells us that, in order to compute what maps must arise from all the mapping cones, it is enough to treat the special case where the exact category is $\mathcal{A} \subset D^b(\mathcal{A})$. But then, the rectangle with the frame of dashes around it is determined uniquely, from the rest of the diagram, by pullback. This makes the computation somewhat easier.

The third and easiest way is to observe that we have a commutative square

\[
\begin{array}{ccc}
0 & \rightarrow & Y_{0j} \\
\uparrow & & \uparrow \\
Z_{jk} \oplus X_{p0} & \rightarrow & Y_{0k} \oplus X_{NW}
\end{array}
\]

The map $Z_{jk} \oplus X_{p0} \rightarrow Y_{0k} \oplus X_{NW}$ is defined in some universal way out of mapping cones on triangles from $s_n$. In particular, the map itself is a matrix in maps from $s_n$. The map is a matrix

\[
\begin{pmatrix}
a & b \\ 
c & d
\end{pmatrix}
\]

and there is really no freedom for $a$, $c$ and $d$. But the composite

\[
X_{NW} \rightarrow Y_{0k} \oplus X_{NW} \rightarrow Y_{0j}
\]

must be zero, and since this is universally true (=for all choices of simplices) it is easy to deduce that $b = -\beta$.

Coming back to the proof of Lemma 7.6, we note that we have so far constructed a homotopy which we denoted by

\[
/ X_{NW}^{<1}
\]

This homotopy links the identity with a map which we naturally denote
And the point is that this map factors through the simplicial set

which is almost the same as the nerve of the category of monoeps; the difference is that we keep track of the kernels, and of a map \( X_{NW}^{<1} \rightarrow Y_j \). Precisely, an \( n \)-simplex \( s_n \) in the simplicial set

is a diagram of \( M - V \) squares
Once again, we have framed the $X_{NW}$, as it is fixed. The fact that the map

factors through

is essentially immediate; all the data we need to reconstruct the image of the simplex $s_n$ is contained in a subsimplex which really lies in
But we know more. We have really factored the identity quite explicitly. Precisely, we have constructed two maps

The maps $\theta$ and $\phi$ are really quite obvious. Let us however compute them once explicitly. An $n$-simplex $s_n$ in the simplicial set

is a diagram
An $n$–simplex $t_n$ in the simplicial set $X_{NW}$ is a diagram
The map $\phi$ takes the simplex $s_n$ to the simplex

whereas the map $\psi$ takes $t_n$ to the simplex
The composites $\phi \circ \theta$ and $\theta \circ \phi$ are quite explicit. The beginning of the lemma proved that $\phi \circ \theta$ is homotopic to the identity. But $\theta \circ \phi$ takes the simplex $t_n$ to the diagram
and the point is that this can be viewed as a translation with respect to some \( H \)--space structure. Precisely, there is a map

\[
\begin{array}{ccc}
0 & \xrightarrow{\left(0, X_{NW}^{<1}\right)} & T_{[0,n]}^{1} \\
\uparrow & & \uparrow \\
\cdots & & \cdots \\
0 & \xrightarrow{T_{[0,n]}^{1} X_{NW}^{<1}} & \cdots \rightarrow Z_{\alpha n} \rightarrow Y_{0} \oplus X_{NW}^{<1} \\
\uparrow & & \uparrow \\
X_{NW}^{<1} & & X_{NW}^{<1}
\end{array}
\]

This map is induced by forming direct sums, and then dividing by the diagonal inclusion of \( X_{NW}^{<1} \). The map \( \theta \circ \phi \) is translation by the 0--cell

\[
0 \rightarrow X_{NW}^{<1} \\
X_{NW}^{<1} \rightarrow X_{NW}^{<1}
\]

with respect to this action. This action gives a true \( H \)--space (unlike some other actions we will soon be considering on the same space). In particular, there is a
neutral element for the action, the 0-cell

\[ 0 \rightarrow X_{NW}^{<1} \]

As we will see in the proof of Lemma 7.11, the simplicial set

\[
\begin{array}{c}
\text{0} \\
\downarrow \\
T_{[0,n]}^{A} \\
\downarrow \\
X_{NW}^{<1}
\end{array}
\]

is connected. Translation by any 0-cell is homotopic to the identity. That proves that \( \theta \circ \phi \) is homotopic to the identity. \( \square \)

Remark 7.10. The reason the author has gone over the argument so carefully this time is that arguments like the above seem to be ubiquitous in this theory. One is always led to considering translations with respect to \( H \)-space structures, some of which are slightly fake. A fine example of this is Lemma 7.11.

The strategy of the proof of Theorems 4.8 and 7.1 is to show that the simplicial set

\[
\begin{array}{c}
\text{0} \\
\downarrow \\
T_{[0,n]}^{A} \\
\downarrow \\
X_{NW}^{<1}
\end{array}
\]

is contractible. But there is still the nuisance \( X_{NW}^{<1} \) hanging off the bottom. We want to get rid of it.

Lemma 7.11. Suppose \( \mathcal{T} = D^b(\mathcal{A}) \) with the usual \( t \)-structure, or \( \mathcal{T} = G^b_t(\mathcal{A}) \). If the simplicial set

\[
\begin{array}{c}
\text{0} \\
\downarrow \\
T_{[0,n]}^{A} \\
\downarrow \\
\text{0}
\end{array}
\]

is contractible, then for any \( A \) an object of \( T_{[0,0]} \), the simplicial set
must also be contractible.

Proof. First observe that both simplicial sets are connected. (This is the part for which we need \( T = D^b(A) \) with the usual t-structure, or \( T = Gr^b(A) \).) For \( T = Gr^b(A) \), the connectedness is obvious. Suppose therefore \( T = D^b(A) \). If

\[
\begin{array}{ccc}
0 & \longrightarrow & X \\
& & \\
& & A \\
\end{array}
\]

is a 0-cell in

\[
\begin{array}{ccc}
0 & \longrightarrow & T_{[0,n]} \\
& & \\
& & A \\
\end{array}
\]

then we write \( X \in D^b(A) \) as a complex

\[
\cdots \longrightarrow X^{-1} \longrightarrow X^0 \longrightarrow X^1 \longrightarrow \cdots
\]

and there is a map from \( X \) to its “brutal” truncation

\[
\begin{array}{ccc}
\cdots & \longrightarrow & X^{n-1} \\
\downarrow & & \downarrow \\
\cdots & \longrightarrow & X^{n} \\
\downarrow & & \downarrow \\
\cdots & \longrightarrow & X^{n+1} \\
& & \downarrow \\
\cdots & \longrightarrow & 0 \\
& & \downarrow \\
\cdots & \longrightarrow & 0 \\
& & \downarrow \\
\cdots & \longrightarrow & \cdots
\end{array}
\]

This gives a truncation \( X \rightarrow X^{tr} \), which is clearly monoepi if \( n \geq 1 \). But the map \( A \rightarrow X^{tr} \) is also monoepi. If one keeps track of the kernels in the computation, this connects the simplex

\[
\begin{array}{ccc}
0 & \longrightarrow & X \\
& & \\
& & A \\
\end{array}
\]

to the simplex

\[
\begin{array}{ccc}
0 & \longrightarrow & A \\
& & \\
& & A \\
\end{array}
\]

and we immediately deduce connectedness.
Now the point is that for any $A$, the realization of

\begin{equation}
\begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
A
\end{array}
\end{equation}

is a fake $H$–space, with the operation given by direct sum. The reason it is fake is because it is not \emph{a priori} clear that there is an identity element. Note that this is different from the true $H$–space structure we considered, on the same space, on page 474. The true $H$–space structure was not just direct sum, but direct sum followed by division by some inclusion. Anyway, there is a multiplication map

\begin{equation}
\begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
A
\end{array} \times \begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
A
\end{array} \xrightarrow{\text{multiplication}} \begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
A
\end{array}
\end{equation}

There is also an action of

\begin{equation}
\begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
0
\end{array} \text{ on } \begin{array}{c}
\text{(0)} \\
\uparrow \\
\text{[0, n]} \\
\downarrow \\
A
\end{array}
\end{equation}

again induced by direct sums. The idea of the proof will be to compare these actions.

The first observation is that the two maps
are homotopic, because by assumption

is contractible. In particular, we deduce that the composite
is homotopic to the identity. Here, $\Delta$ is the diagonal map. But concretely, this composite is the simplicial map sending the $n$-simplex

$$y_n = \begin{pmatrix}
0 & \rightarrow & Y_n \\
\vdots & \vdots & \vdots \\
0 & \rightarrow & Z_0 & \rightarrow & \cdots & \rightarrow & A \\
\end{pmatrix}$$

to the simplex
where \( i_2 : A \to Y_0 \oplus Y_0 \) is the inclusion in the second summand.

Now, up to a canonical automorphism of \( Y_0 \oplus Y_0 \), the map \( i_2 \) is equal to the diagonal; this immediately shows that the identity is homotopic to the map taking the \( n \)-simplex \( y_n \) to

\[
0 \to Y_n \oplus Y_n \\
\hspace{2cm} \cdots \\
\hspace{2cm} Z_{0n} \oplus Z_{0n} \to Y_0 \oplus Y_0
\]

and this map is nothing other than the composite
Next we will make a small computation in the homotopy groups of

Because the homotopy groups of a space are a based invariant, let us choose a base
point,

We will show the vanishing of

$$\Pi_* \left( \begin{pmatrix} 0 & \nabla [0,n] \\ A \end{pmatrix} \right) \times \left( \begin{pmatrix} 0 & \nabla [0,n] \\ A \end{pmatrix} \right)$$
for every $i \geq 1$. Because we already know the connectedness of the space, this proves contractibility.

**Remark 7.12.** Thomason pointed out that it is unnecessary to make this computation in the homotopy groups; one can argue more directly. This is of course true, but I wanted to underline the fact that we are only computing the higher homotopy of the space. This argument most definitely does not show the connectedness.

We need to show that any based map from a sphere into the pair

$$\left( \left( \begin{array}{c} 0 \\ \mathcal{F}_{[0,n]} \\ \downarrow \\ A \end{array} \right), \left( \begin{array}{ccc} 0 & \rightarrow & A \\ \uparrow \\ A \end{array} \right) \right)$$

is null homotopic. Let $\phi$ be such a map. Recall that, if $\mu$ is the multiplication map on

$$\left( \begin{array}{c} 0 \\ \mathcal{F}_{[0,n]} \\ \downarrow \\ A \end{array} \right),$$

we know that the composite
is homotopic to the identity, by a homotopy that does not preserve the basepoint. Therefore the composite \( \mu \circ \Delta \circ \phi \) is homotopic to \( \phi \), by a homotopy which need not preserve the base point. We will show that \( \mu \circ \Delta \circ \phi \) is null homotopic. This shows first that \( \phi \) is null homotopic by a homotopy not preserving the basepoint, but this homotopy can be adjusted to one preserving basepoints.

The point is that \( \Delta \circ \phi \) is a map from a sphere into a product. It is therefore homotopic to a sum \( \alpha_1 \oplus \alpha_2 \) of two maps which factor through sections \( i_1 \) and \( i_2 \) of the product, respectively. It then suffices to show that \( \mu \circ \alpha_j \) is null homotopic, for \( j = 1, 2 \). Even better, it suffices to prove that \( \mu \circ i_j \) is null homotopic for \( j = 1, 2 \). As this is symmetric, it suffices to consider \( i_1 \).

But the map \( \mu \circ i_1 \) is easy to compute. It takes the simplex

\[
y_n = \left( \begin{array}{c}
0 \\
\vdots \\
\vdots \\
0 \\
\end{array} \right) \rightarrow Y_n
\]

\[
y_n = \left( \begin{array}{c}
Z_0n \\
\vdots \\
\vdots \\
A \\
\end{array} \right) \rightarrow Y_0
\]
to the simplex

\[
\begin{array}{c}
0 \\ \\
\vdots \\ \\
0 \\
\end{array} \longrightarrow \cdots \longrightarrow Z_{0n} \longrightarrow Y_0 \oplus A
\]

But once again, up to a canonical automorphism of $Y_j \oplus A$, the diagonal equals the inclusion $i_2$ in the second factor. Thus the map $\mu \circ i_1$ factors through

\[
0 \xrightarrow{f_{[0,n]}} A
\]

which is contractible.

\[\square\]

**Caution 7.13.** Let us elaborate a little on Remark 7.12. As we said, it is essential for the space

\[
0 \xrightarrow{f_{[0,n]}} A
\]

to be connected in the above argument. To illustrate this point, suppose that instead of proceeding with the particular simplicial sets we chose, we replaced them with others. Precisely, suppose that instead of working with the diagram
we decide to look at the diagram
To make the difference easier to see, I have highlighted it with a dashbox. The vertical morphisms at the bottom of the diagram are no longer restricted to be mono.

Then most of the argument goes through unaltered. The map $f'_1$ is still trivially a homotopy equivalence. The homotopy of Lemma 7.6 still works, to show that the identity on the Segal fiber factors as $\partial\theta$ below.
But this is as far as we get unscathed. The space

most definitely is not connected. It is still a fake $H$–space with respect to direct sum, and there is still an action of

on it. The argument of Lemma 7.11 still proves that as long as

is contractible, so must also be the connected component of
at the obvious basepoint. But that is all.

Lemma 7.11 seems to be a very useful trick in triangulated $K$–theory, and we will have occasion to use it in subsequent papers. Let us therefore formalise as a proposition the topological statement we used.

**Proposition 7.14.** Let $X$ and $Y$ be topological spaces. Suppose $X$ is contractible and $Y$ is connected. Suppose $X$ is an $H$–space, suppose $X$ acts on $Y$, and suppose $Y$ is a fake $H$–space (i.e. there is a product, but no neutral element). Let the action be denoted

$$X \times Y \xrightarrow{\Delta} Y$$

and let the fake $H$–space structure be denoted

$$Y \times Y \xrightarrow{\mu} Y.$$

Suppose there is a map $\alpha : Y \to X$ such that the two composites

$$Y \xrightarrow{\begin{pmatrix} \alpha & 1 \end{pmatrix}} X \times Y \quad \text{and} \quad Y \xrightarrow{\Delta} Y \times Y$$

are homotopic, and suppose further that for both inclusions of $Y$ as a section of $Y \times Y$, the composites

$$Y \xrightarrow{\begin{pmatrix} * & 1 \end{pmatrix}} Y \times Y \quad \text{and} \quad Y \xrightarrow{\begin{pmatrix} 1 & * \end{pmatrix}} Y \times Y$$

are null homotopic. Then $Y$ has the weak homotopy type of a contractible space. □

For Constructions 4.6 and 4.7 we can do better; we will prove:

**Lemma 7.15.** For $Gr(\mathcal{A})$, we have that the projection
is a quasi-fibration. The homotopy fiber is

\[ \begin{array}{c}
0 \\
\uparrow \\
Gr_{[0,n]} \\
\uparrow \\
0
\end{array} \xrightarrow{f_2} \\
\begin{array}{c}
0 \\
\uparrow \\
Gr_{[0,n]} \\
\uparrow \\
0
\end{array} \]

Remark 7.16. This is of value especially in the case of Construction 4.6, i.e. without the differentials. We will not be able to show the contractibility of the homotopy fiber; but knowing that it is the homotopy fiber will allow us nevertheless to make some deductions.

Since this is the first place in the article in which we prove a map to be a quasi-fibration, it seems only right to explain what to do in some detail. All future proofs that maps are quasi-fibrations will follow the same pattern.

The topological fact which we use is

Theorem 7.17. (Quillen’s Theorem B). Let S. be a simplicial space, T. a simplicial set. Suppose \( F : S. \to T. \) is a simplicial map (i.e. a simplicial map of simplicial spaces, where T. is declared to be a simplicial space with the discrete topology). Pick \( X \in T_n \), then we call \( f^{-1}(X) \) the fiber in S. over the n-simplex X. Suppose that for every X and every face map \( \partial : T_n \to T_{n-1} \), the induced map \( f^{-1}(X) \to f^{-1}(\partial X) \) is a homotopy equivalence. Then the realization of \( F \) is a quasi-fibration.

Proof of Lemma 7.15. We need to show that the map
induces a quasifibration. If we realize first the simplicial structure that becomes
degenerate on the target, we have a map from a bisimplicial space to a bisimplicial
set, to which we can now apply Quillen’s Theorem B, as above. Thus, it would suffice
to prove that the face maps on the fibers, defined as in Quillen’s Theorem B, all
induce homotopy equivalences.

But Step 2 established a homotopy equivalence

And because the maps $\alpha$ and $\beta$ are so explicit, we can compute for any face map $\partial$
the composite
To prove \( \partial \) a homotopy equivalence, it suffices to prove that the composite \( \beta \circ \partial \circ \alpha \) is.

Our argument will run as follows. We will prove that, for any \( A \), the map

\[
0 \rightarrow Gr_{[0,n]} \rightarrow A
\]

which forgets \( A \) induces a homotopy equivalence. There is a candidate inverse.
namely the map sending the simplex

\[
\begin{array}{c}
0 \\
\vdots \\
0 \rightarrow \cdots \rightarrow Z_{0n} \rightarrow Y_0 \\
0
\end{array}
\]

to the simplex

\[
\begin{array}{c}
0 \\
\vdots \\
0 \rightarrow \cdots \rightarrow Z_{0n} \rightarrow Y_0 \oplus A \\
A
\end{array}
\]
i_2 being the inclusion into the second summand. It is easy to show that φ ◦ ψ is homotopic to 1.

Let us grant for now that ψ ◦ φ is also a homotopy equivalence. We will come back to proving this before long; for now let us see how this can be used to complete the proof of the Lemma 7.15.

Study the composite φ ◦ β ◦ θ ◦ α ◦ ψ. It is quite explicit and computable; the reader will easily verify that it is simply a translation in the \(H\)-space structure on
In particular, it is a homotopy equivalence. And because so are \( \phi, \beta, \alpha, \) and \( \psi, \) it follows that \( \partial \) is a homotopy equivalence too.

It therefore remains to prove that \( \phi \) and \( \psi \) are homotopy equivalences, and by the remarks above we need only show that \( \psi \circ \phi \) is homotopic to the identity.

Let \( y_n \) be an \( n \)-simplex in

The map \( \psi \circ \phi \) is easily computed to take this simplex

\[
y_n = \begin{pmatrix}
0 & \rightarrow & Y_n \\
\vdots & \uparrow & \vdots \\
0 & \rightarrow & \cdots & \rightarrow & Z_{0n} & \rightarrow & Y_0 \\
& & & & \uparrow & & \\
& & & & A & & 
\end{pmatrix}
\]

to the simplex
This is of course translation in the fake $H$–space structure. But now write down a homotopy whose cells are

$$
\psi \circ \phi(y_n) = \begin{pmatrix}
0 & \rightarrow & Y_n \oplus A \\
& \uparrow & \\
& \vdots & \\
& \downarrow & \\
0 & \rightarrow & \cdots & \rightarrow & Z_{0n} & \rightarrow & Y_0 \oplus A \\
& & \uparrow & \\
& & \Delta & \\
& & A
\end{pmatrix}
$$

The point about this homotopy is that $A \rightarrow Y_j^{<1}$ is clearly monoepl. It is mono by hypothesis, and epi because $Y_j^{<1}$ has no higher homology. This makes the right hand column a column of monoeplis, and anyone can compute the kernels; we have disturbed our original simplex by a simplex in the rigid $K$–theory of $A$. 
So far, this is not special to $Gr$. But now we observe that the inclusion $A \longrightarrow Y_j \oplus Y_j^{<0}$ factors canonically through $A \longrightarrow Y_j$. This is very special to $Gr$, and we deduce a homotopy having cells

$$
\begin{array}{c}
0 \\
\downarrow \\
\vdots \\
\downarrow \\
0 & \longrightarrow & \cdots & \longrightarrow & Z_{i+1} \oplus C_{i+1} & \longrightarrow & Y_i \oplus Y_i^{<1} \\
\downarrow \\
\vdots \\
\downarrow \\
0 & \longrightarrow & \cdots & \longrightarrow & Z_i \oplus A_i & \longrightarrow & Y_i \\
\downarrow \\
\vdots \\
\downarrow \\
0 & \longrightarrow & \cdots & \longrightarrow & Z_0 \oplus A_0 & \longrightarrow & \cdots & \longrightarrow & Z_0 \oplus A_0 & \longrightarrow & Y_0
\end{array}
$$

and with these two homotopies we have connected the map $\psi \circ \phi$ with the identity. ☐

From now on we will deal only with the simplicial sets

$$
\begin{array}{c}
0 \\
\uparrow \\
\uparrow \\
\uparrow \\
0
\end{array}
$$

In every case, Lemma 7.11 tells us that their contractibility would establish Theorem 7.1 or 4.8. In the case of $Gr_{[0,n]}(A)$, we have proved the stronger statement that this is the homotopy fiber. Henceforth, we will drop the 0 at the bottom; we will denote this simplicial set by

$$
\begin{array}{c}
0 \\
\uparrow \\
\uparrow \\
\uparrow \\
0
\end{array}
$$
8. First proof of Theorem 4.8. Motivation. In broad strokes, the proof goes as follows. Let $F_n$ be the homotopy fiber of the map

Then there is a commutative diagram, whose rows are fibrations

In this section, we will prove two main lemmas:

**Lemma 1.** (=Lemma 8.8) $\alpha_n : F_n \to F_{n+1}$ induces a homotopy equivalence.

**Lemma 2.** (=Lemma 8.10) $\alpha_n : F_n \to F_{n+1}$ is null homotopic.

Taken together, the lemmas establish the contractibility of $F_n$, and hence Theorem 4.8.

From Section 7 we already have a simplicial model for $F_n$, namely the simplicial set

With this simplicial model, Lemma 2 turns out to be trivial, with the one proviso that it uses the coherent differentials. To prove Lemma 1, we will need another simplicial model for $F_n$.

The idea is simple enough. We label an arrow if it happens to be an $H^0$ isomorphism. Consider the simplicial set

which is of course defined by requiring that the vertical maps be $H^0$-isomorphisms. It is very easy to see that the inclusion
induces a homotopy equivalence. Clearly, the simplicial map

also induces a homotopy equivalence. What would be nice is if the map

induced a quasifibration. This would give us another model for the homotopy fiber \( F_n \), and this model is the simplicial set

which is just the fiber over 0. It can easily be shown that the natural inclusion of the smaller simplicial set, where the objects along the bottom line are restricted to lie in \( \mathcal{G}r_{[1,n]} \), that is the set

,
induces a homotopy equivalence. And this last simplicial set is very amenable to proving Lemma 1.

Unfortunately, I have not been able to prove the map

\[
\begin{array}{ccc}
Gr_{[0,n]} & \overset{\Phi}{\longrightarrow} & Gr_{[0,n]} \\
\downarrow & & \downarrow \\
Gr_{[0,n]} & \overset{\Phi}{\longrightarrow} & Gr_{[0,n]}
\end{array}
\]

a quasi-fibration. Actually, even this is not entirely true. I have a proof which works for the construction without the differentials, Construction 4.6. I assure the reader that he does not want to see that proof. The proof involves homotopies defined on the second barycentric subdivision of the fibers.

What we have in this section instead is a very indirect proof of the existence of a homotopy equivalence

\[
\begin{array}{ccc}
0 & \rightarrow & Gr_{[0,n]} \\
\downarrow & & \downarrow \\
Gr_{[0,n]} & \overset{\Phi}{\longrightarrow} & Gr_{[0,n]}
\end{array}
\]

Thus, even without showing that \(\Phi\) is a quasi-fibration, we succeed in proving that the fiber over zero is the homotopy fiber.

The proof occupies Lemmas 8.1–8.7, and it has about it all the feel of a mission to the moon; you go very far out, and come back to a result that is not actually far removed from the starting point.

**End of Motivation**

The virtue of this proof is that right until the very last step, the argument is valid for both Construction 4.6 and Construction 4.7. This will allow us to say some things about Construction 4.6, even though we do not know its homotopy type.

Again, we will break the proof into steps.

**Lemma 8.1.** *The simplicial set*

\[
\begin{array}{ccc}
0 & \rightarrow & Gr_{[0,n]} \\
\downarrow & & \downarrow \\
Gr_{[0,n]} & \overset{\Phi}{\longrightarrow} & Gr_{[0,n]}
\end{array}
\]

*is also the homotopy fiber of the map*
(For the unmotivated reader, that is one who skipped the motivation, we recall what an arrow \( \xrightarrow{\bullet} \) is. Such a map is an \( H^0 \)-isomorphism.)

More precisely, there is a map

\[
\begin{array}{ccc}
G\text{r}_{[0,n]} & \xrightarrow{tr} & G\text{r}_{[1,n]} \\
\downarrow & & \downarrow \\
0 & \ x & \ x \\
\end{array}
\]

which simply replaces the zeroth cohomology group by 0 (the truncation). The reader will check that it preserves squares and preserves differentials (if any). Therefore, it is a well-defined bisimplicial map. We are asserting that the composite

\[
\begin{array}{ccc}
G\text{r}_{[0,n]} & \xrightarrow{tr} & G\text{r}_{[1,n]} \\
\downarrow & & \downarrow \\
0 & \ x & \ x \\
\end{array}
\]

has for its homotopy fiber the simplicial set

\[
\begin{array}{cc}
\xrightarrow{} & \\
0 & \ x \\
\end{array}
\]

Proof. Consider the trisimplicial set and the two projections:
It is very easy to prove that $f_2$ is a homotopy equivalence; the fiber

is contractible, the contracting homotopy being
This is of course the contraction to the terminal object; the homotopy send the cell

$$
\begin{array}{c}
\xymatrix{ X_{r0} & \cdots & X_{pq} & Y_{r0} & \cdots & Y_{pr} \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
X_{00} & \cdots & X_{0q} & Y_{00} & \cdots & Y_{0r} \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
Z_{r0} & \cdots & 0 \\
\vdots & \vdots & \\
0 & \vdots & \vdots \\
\end{array}
$$

to the collection of $q + 1 (q + 1)$-simplices, the $(q - i)^{th}$ of which is
(Note that this homotopy will not work in a triangulated category $\mathcal{T}$; the natural map to the truncation is $Y^0_0 \to Y^\geq_0$).

Thus, to prove Lemma 8.1, it suffices to show that $f_2$ is quasifibration (the fiber over $X = 0$ being right). Once again, we use our favorite homotopy. To apply Quillen’s Theorem B we need to study the Segal fiber of $f_2$. It is the simplicial set

```
X  \xymatrix{ \ar@{->}[rr]^(.35){\downarrow} \ar@{->}[rru] & & \ar@{->}[rr] \ar@{->}[rru] & & \ar@{->}[rr] \\ Gr_{[0,n]} \ar@{->}[rru] & & \ar@{->}[rru] \ar@{->}[rru] & & \ar@{->}[rru] \\ 0 \ar@{->}[ru] & & \ar@{->}[ru] \ar@{->}[ru] & & \ar@{->}[ru] \\
```

and we apply the homotopy
The only thing that needs caution is the proof that the cells of the homotopy do not depart from their simplicial set. The cells of the homotopy are
and the key point is that the cells of the homotopy are legitimate, because the maps inside the dashbox, namely $X_{i_0} \oplus Y_{i_0} \to Y_{ij}$, are indeed mono. The reason we can be certain of this is that $H^0(X_{i_0}) = 0$, and $Y_{i_0} \to Y_{ij}$ is mono.

This proves that the identity on the fiber factors, up to homotopy, through the simplicial set

$$\triangledown$$
and it is easy to check that this factorization induces a homotopy equivalence. The point is that we have two maps

\[ X \xrightarrow{\phi} Gr_0^{[0,n]} \xrightarrow{\theta} Gr_{[0,n]} \]

We have just proved that the composite \( \phi \circ \theta \) is homotopic to the identity. The composite \( \theta \circ \phi \) is easier; it is easily computed to be nothing other than a translation in the \( H \)-space structure of

\[ 0 \xrightarrow{\phi} Gr_{[0,n]} \]

Thus the fibers have a homotopy type independent of \( X \). It is easy to verify that the face maps on \( X \) induce homotopy equivalences of the fibers; see Lemma 7.15. Hence \( f_1 \) is a quasi-fibration. \( \square \)

**Lemma 8.2.** The natural projection

\[ Gr_0^{[0,n]} \xrightarrow{\phi} Gr_1^{[0,n]} \]

is a homotopy equivalence.

**Proof.** The fiber (in the sense of Segal) is the simplicial set
which is contracted by the homotopy

**Lemma 8.3.** *The natural map*
is a homotopy equivalence.

Proof. Study the quarti-simplicial set and two projections
The map $f_1$ is a homotopy equivalence because on the fiber
we can apply the contracting homotopy

The map $f_2$ is slightly trickier. Once again, we must resort to our favorite homotopy. The Segal fiber is the simplicial set
and we need to show it contractible. By the homotopy

the identity on
factors through the simplicial set

which is trivially contractible, by the contraction to the terminal object. \qed

**Remark 8.4.** Note that as the article progresses, the author feels free to leave more to the reader to check. For instance, the reader should check that the homotopy above is well defined, and does not wander away from its simplicial set of definition. In the original version of the article, verifications of this sort were included in painstaking detail. A number of people objected. The present article attempts to create a notation in which it is clear what the homotopies should be, and they can therefore be left to the reader.

**Remark 8.5.** By this time the reader might be getting understandably fidgety about our favorite homotopy. As time goes on, we see more and more variants of it. First we allowed transposes and duals. Then we permitted kernels. Then we allowed ourselves to divide by a fixed subobject. Now we are subdividing the (vertical) simplicial structure. Where will it all end?

The point of Sections II.1 and III.1 is that all the homotopies we have seen, and some more to come, can be obtained by deletion and subdivision from one master homotopy, together with its transpose and duals. This is why Sections II.1 and III.1 were put later rather than earlier in these articles. It is hard to see the point of a master blueprint for the homotopy, unless one has first seen examples.

**Lemma 8.6.** *The projection*
is a homotopy equivalence.

Proof. The Segal fiber is the simplicial set

and it is contracted by the homotopy

\[ \text{Lemma 8.7. The projection} \]

is a quasi-fibration.

Proof. We need to study the fiber
Once again, we apply our very favorite homotopy. Precisely, there is a homotopy

and because this is a slightly new incarnation of our favorite homotopy, we will present its cells. The homotopy takes a cell in

to lots of cells. Precisely, given a \((q,r)\) cell \(s_{(q,r)}\) in the bisimplicial set

the cell defines a diagram
The homotopy we will give will be a horizontal homotopy. It is defined by cells which increase the integer $q$, but leave $r$ unchanged. It can be thought of as giving a homotopy first on each horizontal realisation, and these homotopies glue to define a global homotopy when we also realise the simplicial structure that corresponds to varying $r$.

To our starting cell $s_{(q,r)}$ we must associate $q + 1 (q + 1, r)$ cells. The $(q - i)^{th}$ is given by the diagram
The notation for the homotopy is meant to be self-explanatory. The part enclosed in a dashbox below

\[
\begin{array}{c}
Y_{r_0} \rightarrow \cdots \rightarrow Y_{r_i} \rightarrow Y_{r+1N} \rightarrow \cdots \rightarrow Y_{r_qN}
\end{array}
\]

\[
Y_{0_0} \rightarrow \cdots \rightarrow Y_{0_i} \rightarrow Y_{0+1N} \rightarrow \cdots \rightarrow Y_{0_qN}
\]

\[
X_{p_0} \rightarrow \cdots \rightarrow X_{p_i} \rightarrow X_{p+1N} \rightarrow \cdots \rightarrow X_{p_qN} \rightarrow Z_{p_0} \rightarrow \cdots \rightarrow Z_{p_e}
\]

\[
X_{0_0} \rightarrow \cdots \rightarrow X_{0_i} \rightarrow X_{0+1N} \rightarrow \cdots \rightarrow X_{0_qN} \rightarrow Z_{0_0} \rightarrow \cdots \rightarrow Z_{0_e}
\]

(i+1) terms

(q-i+1) terms

is nothing other than our favorite old homotopy, quite untampered. But what we next enclose in a dashbox represents the fact that in the top right hand box, the homotopy adds a $Z_{NW}$. 
The reader should note that in Proposition 7.9 we have already computed the map

\[ X_{pk} \oplus Z_{NW} \to Y_{0k} \oplus Z_{NW}. \]

It is the matrix

\[
\begin{pmatrix}
\alpha & 0 \\
-\beta & 1
\end{pmatrix}
\]

where \( \alpha : X_{pk} \to Y_{0k} \) and \( \beta : X_{pk} \to Z_{NW} \) are the natural structural morphisms of the simplex \( s_{(q, r)} \). This also is reflected in the notation for the homotopy. The homotopy connects the identity with a map we might naturally call

and, as the notation should suggest, this map factors through the simplicial set

Another way we have been writing this simplicial set is
The point is that a simplex in this simplicial set should be thought of as a simplex in

\[
\begin{array}{c}
\text{Gr}_{[0,n]} \\
\text{Gr}_{[1,n]}
\end{array}
\]

together with a map from the bottom line, which I have conveniently highlighted with a dashbox, to the fixed object $Z_{NW}$.

This map to $Z_{NW}$ is a nuisance. We want to prove some map a quasifibration, and this means that the homotopy type of the fiber should be independent of $Z$. We have deduced thus far that the identity on

\[
\begin{array}{c}
\text{Gr}_{[0,n]} \\
\text{Gr}_{[1,n]}
\end{array}
\]

factors up to homotopy through the map

\[
\begin{array}{c}
\text{Gr}_{[0,n]}@>>> Z_{NW} \\
\text{Gr}_{[1,n]}@>>> Z
\end{array}
\]

And now we follow by another homotopy, this time vertical, which we denote
The cells of this homotopy are
The last map clearly exhibits that, up to homotopy, the identity on the fiber factors through the bisimplicial set.

And thus we are rid of the nuisance map to $Z_{NW}$. More precisely, there are maps.
We have just proved that $\psi \circ \phi$ is homotopic to the identity. But one can easily compute $\phi \circ \psi$ and show it to be a translation in the $H$–space structure of the connected space.

This proves that the homotopy type of the fiber is independent of $Z$. An easy computation, left to the reader, shows that the face maps are homotopy equivalences. See also the proof of Lemma 7.15.

**Conclusion of Lemmas 8.1–8.7.** What we have done so far is establish, in a somewhat roundabout way, that there is a homotopy equivalence between realizations of

It follows from Lemmas 8.1–8.7 that both are the homotopy fibers of the same map. Now we come to the crux of the matter.

**Lemma 8.8.** The inclusion

induces a homotopy equivalence.

**Proof.** We factor the inclusion as the composite
where a morphism $X \to Y$ in $Gr_{[0,n]}$ is said to be $\cong$ if for all $2 \leq i \leq n$, it induces $H^i$-isomorphisms (of course, a morphism $\cong$ induces $H^i$-isomorphisms for $i = 0$ and $2 \leq i \leq n$).

Truncation above dimension 1 clearly gives a homotopy inverse for the map $\alpha$. The homotopy inverse of the map $\beta$ is also quite explicit. Take a $(p,q)$-simplex $y_{(p,q)}$ in

Such a simplex is a diagram

$$
\begin{align*}
Y_{p0} & \hookrightarrow \cdots \hookrightarrow Y_{pq} \\
\vdots & & \vdots \\
Y_{00} & \hookrightarrow \cdots \hookrightarrow Y_{0q} \\
X_0 & \hookrightarrow \cdots \hookrightarrow X_q
\end{align*}
$$

and the homotopy inverse of $\beta$ sends it to
\[ Z_{p0} \leftrightarrow \cdots \leftrightarrow Z_{pq} \]
\[ Z_{00} \leftrightarrow \cdots \leftrightarrow Z_{0q} \]
\[ X_0 \leftrightarrow \cdots \leftrightarrow X_q \]

where \( Z_{ij} \) is defined as follows:

8.8.1. \( H^0(Z_{ij}) = H^0(Y_{ij}) \)

8.8.2. \( H^k(Z_{ij}) = H^k(X_j) \) for \( 2 \leq k \leq n \)

8.8.3. \( H^1(Z_{ij}) = \text{Im}(H^1(X_j) \to H^1(Y_{ij})) \).

The reader will check that the map given above is a bisimplicial map, and that both composites are homotopic to the identity.

\[ \square \]

Remark 8.9. Perhaps a less mysterious description of this map is as follows. Let \( F_i \) be the third edge in the “triangle” \( F_i \to X_j \to Y_{ij} \). Then \( Z_{ij} \) is the third edge of the triangle \( H^1(F_i) \to X_j \to Z_{ij} \) (note that \( F_i \in D_{[1,n+1]} \) in general. There is no epi-ness hypothesis.)

It should also be remarked that the category \( Gr \) has this property that one can define on it strange homotopies that do not fall into the simple categories we will discuss in Sections II.1 and III.1. The triangulated proof is harder, but it is also free of “spurious” homotopies.

Up until this point, everything we have done is valid in both Constructions 4.6 and 4.7. The next step is not.

Lemma 8.10. The inclusion

\[ Gr_{[0,n+1]} \rightarrow Gr_{[0,n]} \]

is null homotopic.

Proof. We leave to the reader the fact that the identification
is natural in $n$; it suffices therefore to show that

$$
\begin{array}{ccc}
0 & \to & Gr_{[0,n]} \\
\uparrow & & \uparrow \\
Gr_{[0,n+1]} & \to & 0
\end{array}
$$

is null homotopic. But this inclusion factors as

$$
\begin{array}{ccc}
0 & \to & Gr_{[0,n]} \\
\uparrow & \leftarrow & \uparrow \\
Gr_{[0,n]} & \to & 0
\end{array}
\begin{array}{ccc}
0 & \to & Gr_{[0,n]} \\
\uparrow & \leftarrow & \uparrow \\
Gr_{[0,n+1]} & \to & 0
\end{array}
$$

(this is just the fact that any morphism in $Gr_{[0,n]}$ is epi, when viewed in $Gr_{[0,n+1]}$).

On the other hand

$$
\begin{array}{ccc}
0 & \to & Gr_{[0,n]} \\
\uparrow & \leftarrow & \uparrow \\
Gr_{[0,n]} & \to & 0
\end{array}
$$

(because for the symmetric construction, the one where differentials are kept, kernels and cokernels are the same). And the simplicial set on the right is clearly contractible, by the contraction to the initial object. \qed

This completes the proof of Theorem 4.8.

**Appendix A. Semi-triangles.** We remind the reader that this Appendix contains only a sketch of an argument the author never checked carefully. Since the author has forgotten any detail he may have thought about, when he wrote these notes four years ago, he will stick closely to the old notes. It is more probable that they are correct than what he might try to write now.

Let $\mathcal{T}$ be a triangulated category. We define

**Definition A.1.** In the triangulated category $\mathcal{T}$, a sequence

$$x \xrightarrow{u} y \xrightarrow{v} z \xrightarrow{w} \Sigma x$$

is called a candidate triangle if the three composites

$$vu, \quad vw, \quad \{\Sigma u\} w$$

all vanish.

**Definition A.2.** A candidate triangle is called contractible if it is isomorphic to a sum of three trivial candidate triangles

$$
\begin{array}{cccc}
x & \xrightarrow{1} & x & \xrightarrow{0} & \Sigma x \\
0 & \xrightarrow{1} & y & \xrightarrow{0} & 0 \\
\Sigma^{-1} z & \xrightarrow{1} & 0 & \xrightarrow{z} & z
\end{array}
$$
Having defined candidate triangles, and defined which of them we view as contractible, it is now time to define morphisms between them. A morphism of candidate triangles is a commutative diagram:

\[
\begin{array}{cccccc}
  x & \xrightarrow{u} & y & \xrightarrow{v} & z & \xrightarrow{w} & \Sigma x \\
  f & & g & & h & & \Sigma f \\
  x' & \xrightarrow{u'} & y' & \xrightarrow{v'} & z' & \xrightarrow{w'} & \Sigma x'
\end{array}
\]

With this definition, the collection of candidate triangles forms a category. We denote this category \( CT(\mathcal{T}) \). Given a morphism of candidate triangles as above, its mapping cone is the diagram:

\[
\begin{array}{cccccc}
  y \oplus x' & \xrightarrow{z \oplus y'} & \Sigma x \oplus z' & \xrightarrow{\Sigma y \oplus \Sigma x'} \\
  & & & \end{array}
\]

The mapping cone construction takes a morphism in \( CT(\mathcal{T}) \) to an object of \( CT(\mathcal{T}) \).

**Definition A.3.** The subcategory \( ST(\mathcal{T}) \subset CT(\mathcal{T}) \) is the smallest full subcategory which

A.3.1. Contains all the distinguished triangles.

A.3.2. Contains the mapping cone on any map of its objects.

A.3.3. If \( C \) is a candidate triangle in \( ST(\mathcal{T}) \), and \( C \) is isomorphic to a direct sum \( C' \oplus C'' \) with \( C' \) contractible, then \( C'' \in ST(\mathcal{T}) \).

An object of \( ST(\mathcal{T}) \) will be called a semi-triangle in \( \mathcal{T} \).

**Remark A.4.** According to my notes, it should be obvious that any semi-triangle is a direct summand of a good semi-triangle of height \( n, n \in \mathbb{Z} \). The semi-triangles of height \( n \) are defined inductively, as follows:

A.4.1. The semi-triangles of height 0 are the distinguished triangles.

A.4.2. A semi-triangle of height \( n + 1 \) is the mapping cone on a map of candidate triangles \( C \rightarrow C' \), where \( C \) is a distinguished triangle, and \( C' \) is a semi-triangle of height \( n \).

**Example A.5.** Let \( \mathcal{A} \) be an abelian category, \( \mathcal{T} = D(\mathcal{A}) \) its derived category. Given any short exact sequence in \( \mathcal{A} \), that is a sequence

\[
0 \rightarrow x \rightarrow y \rightarrow z \rightarrow 0
\]

there is a unique differential making it a triangle; there is a unique morphism \( w : z \rightarrow \Sigma x \) so that

\[
x \rightarrow y \rightarrow z \xrightarrow{w} \Sigma x
\]

is a triangle in \( \mathcal{T} \). We have a morphism of triangles:

\[
\begin{array}{cccccc}
  \Sigma^{-1} z & \xrightarrow{-\Sigma^{-1} w} & x & \xrightarrow{-u} & y & \xrightarrow{-v} & z \\
  \Sigma^{-1} w & & 0 & & 0 & & \Sigma x \\
  x & \xrightarrow{u} & y & \xrightarrow{v} & z & \xrightarrow{w} & \Sigma x
\end{array}
\]
and the mapping cone is

\[
\begin{pmatrix}
  u & 0 \\
  0 & u \\
\end{pmatrix} \quad \begin{pmatrix}
  v & 0 \\
  0 & v \\
\end{pmatrix} \quad \begin{pmatrix}
  w & 0 \\
  0 & w \\
\end{pmatrix}
\]

\[
x \oplus x \quad \rightarrow \quad y \oplus y \quad \rightarrow \quad z \oplus z \quad \rightarrow \quad \Sigma x \oplus \Sigma z .
\]

This is a semi-triangle, being the mapping cone on a map of triangles. However, it is not in general a distinguished triangle. The sequence

\[
\begin{align*}
0 & \quad \rightarrow \quad x \oplus x \\
& \quad \rightarrow \quad y \oplus y \\
& \quad \rightarrow \quad z \oplus z \\
& \quad \rightarrow \quad 0
\end{align*}
\]

is a short exact sequence in the abelian category \( A \subset D(A) = T \). The unique way to extend it to a triangle is as

\[
\begin{pmatrix}
  u & 0 \\
  0 & u \\
\end{pmatrix} \quad \begin{pmatrix}
  v & 0 \\
  0 & v \\
\end{pmatrix} \quad \begin{pmatrix}
  w & 0 \\
  0 & w \\
\end{pmatrix}
\]

\[
x \oplus x \quad \rightarrow \quad y \oplus y \quad \rightarrow \quad z \oplus z \quad \rightarrow \quad \Sigma x \oplus \Sigma z .
\]

But the matrices

\[
\begin{pmatrix}
  w & 0 \\
  0 & w \\
\end{pmatrix} \quad \begin{pmatrix}
  w & 0 \\
  w & w \\
\end{pmatrix}
\]

will agree only if \( w = 0 \). In other words, the semi-triangle above is a triangle precisely if \( w = 0 \), that is precisely if the short exact sequence

\[
0 \rightarrow x \rightarrow y \rightarrow z \rightarrow 0
\]

is split.

**Definition A.6.** Let \( T \) be a triangulated category. The simplicial set

\[
\begin{tikzpicture}
\node (T) at (0,0) {\texttt{\( T \)}};
\node (X00) at (-2,-2) {\texttt{\( X_{00} \)}};
\node (Xpq) at (-2,2) {\texttt{\( X_{pq} \)}};
\node (X0q) at (-2,0) {\texttt{\( X_{0q} \)}};
\node (Xp0) at (-2,-1) {\texttt{\( X_{p0} \)}};
\node (Xp1) at (-2,-1.5) {\texttt{\( \cdots \)}};
\node (Xp2) at (-2,-2) {\texttt{\( \cdots \)}};
\node (Xp3) at (-2,-2.5) {\texttt{\( \cdots \)}};
\node (Xp4) at (-2,-3) {\texttt{\( X_{pq} \)}};
\draw (X00) -- (X0q);
\draw (X00) -- (Xp0);
\draw (X00) -- (Xp1);
\draw (X00) -- (Xp2);
\draw (X00) -- (Xp3);
\draw (X00) -- (Xp4);
\end{tikzpicture}
\]

is defined as follows. The \((p,q)\)-simplices are diagrams in \( T \)

\[
X_{p0} \rightarrow \cdots \rightarrow X_{pq}
\]

\[
\cdots
\]

\[
\cdots
\]

\[
X_{00} \rightarrow \cdots \rightarrow X_{0q}
\]
together with a coherent differential \( d : X_{pq} \rightarrow \Sigma X_{0q} \). Here, a coherent differential \( d : X_{pq} \rightarrow \Sigma X_{0q} \) is a map such that for any \( 0 \leq i \leq i' \leq p, \) \( 0 \leq j \leq j' \leq q \),

\[
X_{ij} \rightarrow X_{i'j} \oplus X_{ij'} \rightarrow X_{i'j'} \xrightarrow{\phi} \Sigma X_{ij}
\]

is a semi-triangle, as in Definition A.3.

We wish to prove Theorem 7.1. The idea is that the proof is the same as the arguments we have been seeing in this article. To do this, we need first define the

simplicial sets

\[
\begin{bmatrix}
\text{X}_{ij} \\
\text{X}_{ij'}
\end{bmatrix}
\]

for any integers \( m \leq n \). The definition is as follows

**Definition A.7.** Let \( \mathcal{T} \) be a triangulated category with a \( t \)-structure. Let \( m \leq n \) be integers. The simplicial set

\[
\begin{bmatrix}
\text{X}_{ij} \\
\text{X}_{ij'}
\end{bmatrix}
\]

is a subset of

\[
\begin{bmatrix}
\mathcal{T}_{m,n}
\end{bmatrix}
\]

Its simplices are defined as follows. The \((p,q)\)-simplices are diagrams in \( \mathcal{T}_{m,n} \)

\[
\begin{array}{cccc}
X_{p0} & \rightarrow & \cdots & \rightarrow X_{pq} \\
\uparrow & & \uparrow & \\
\vdots & & \vdots & \\
\uparrow & & \uparrow & \\
X_{00} & \rightarrow & \cdots & \rightarrow X_{0q}
\end{array}
\]

together with a coherent differential \( d : X_{pq} \rightarrow \Sigma X_{0q} \). As in Definition A.6, a coherent differential \( d : X_{pq} \rightarrow \Sigma X_{0q} \) is a map such that for any \( 0 \leq i \leq i' \leq p, \) \( 0 \leq j \leq j' \leq q \),

\[
X_{ij} \rightarrow X_{i'j} \oplus X_{ij'} \rightarrow X_{i'j'} \xrightarrow{\phi} \Sigma X_{ij}
\]

is a semi-triangle, as in Definition A.3. This means that it is a direct summand of an extension of triangles, as in Remark A.4. We require that the other summand can
be chosen to be a (contractible triangle)

\[ Z \to Z' \to Z'' \xrightarrow{\phi} \Sigma Z \]

with \( Z, Z' \) and \( Z'' \) in \( \mathcal{T}_{[m,n]} \).

Now with the obvious extensions to more elaborate simplicial sets, we can extend the constructions we have seen so far, as well as the constructions in Parts II and III of this article. My notes tell me that the following Lemma is useful in showing that the homotopies that arise are all well-defined.

**Lemma A.8.** Suppose we are given a simplex in

\[ \begin{array}{c}
Y \quad Y' \quad Y'' \\
\uparrow & \\
X \quad X' \quad X''
\end{array} \]

and suppose that the two faces of this simplex

\[ \begin{array}{c}
Y \quad Y' \\
\uparrow & \\
X \\
\end{array}, \quad \begin{array}{c}
Y' \quad Y'' \\
\uparrow & \\
X' \\
\end{array} \quad \begin{array}{c}
X' \quad X'' \\
\uparrow & \\
X \\
\end{array} \]

lie in the smaller simplicial set

\[ \begin{array}{c}
Y \quad Y' \\
\uparrow & \\
X \\
\end{array} \quad \begin{array}{c}
Y' \quad Y'' \\
\uparrow & \\
X' \quad X'' \\
\uparrow & \\
X \\
\end{array} \]

. Then the entire simplex lies in the smaller simplicial set.

**Proof.** As part of the structure of a simplex in

\[ \begin{array}{c}
Y \quad Y' \\
\uparrow & \\
X \\
\end{array}, \quad \begin{array}{c}
Y' \quad Y'' \\
\uparrow & \\
X' \quad X'' \\
\uparrow & \\
X \\
\end{array} \]

, the diagram
\[ Y \longrightarrow Y' \longrightarrow Y'' \]
\[ X \longrightarrow X' \longrightarrow X'' \]

comes with a coherent differential. This gives us a composite of maps in \( CT(T) \)
\[
\begin{array}{c}
X \longrightarrow X' \oplus Y \longrightarrow Y' \longrightarrow \Sigma X \\
\downarrow \quad \downarrow \quad \downarrow \\
X \longrightarrow X'' \oplus Y \longrightarrow Y'' \longrightarrow \Sigma X \\
\downarrow \quad \downarrow \quad \downarrow \\
X' \longrightarrow X'' \oplus Y' \longrightarrow Y'' \longrightarrow \Sigma X'
\end{array}
\]
and it is easy to show that the middle row is a direct summand on the mapping cone of an obvious map from the bottom row to a shift of the top. By hypothesis, the top and bottom row are direct summands of extensions of triangles in \( T_{[m,n]} \). Hence so is the middle row. The other summand can be chosen to be contractible, and the objects lie in \( T_{[m,n]} \). This means that the middle row also satisfies the hypothesis of membership in the simplicial set.

\[ \square \]

**Remark A.9.** At this point, my notes are singularly unhelpful. They assert that, with the simplicial sets as defined above, the proof of Theorem 7.1 goes through; this needs checking, and nothing is said about the details. Anyway, the assertion is that, if the \( t \)-structure on \( T \) is non-degenerate, then the natural inclusion

\[ 
\begin{array}{c}
T_{[0,0]} \\
\uparrow
\end{array}
\longrightarrow
\begin{array}{c}
T \\
\uparrow
\end{array}
\]

induces a homotopy equivalence.

Let us grant the assertion of Remark A.9. We are still not done. The point is that the simplicial set

\[ \square \]

is not isomorphic to Quillen’s construction

on the abelian category \( T_{[0,0]} \). A simplex in

\[ \square \]

is a diagram
together with the choice of a differential. The assertion that all the $X_{ij}$’s lie in the heart $\mathcal{T}_{[0,0]}$ does mean that, if we forget the differential, we have a diagram of bicartesian squares. But now all we know is that the differentials give us semi-triangles, not necessarily distinguished triangles. As long as the triangles were distinguished, the differentials were unique. But once we allow semi-triangles, it is sometimes possible to complete the diagram of bicartesian squares

$$
\begin{align*}
X_{p_0} &\longrightarrow \cdots \longrightarrow X_{p_l} \\
\uparrow &\quad & \quad \uparrow \\
\vdots &\quad & \quad \vdots \\
\uparrow &\quad & \quad \uparrow \\
X_{0_0} &\longrightarrow \cdots \longrightarrow X_{0_q}
\end{align*}
$$

to a simplex in more than one way. There may be more than one choice of differentials. See Example A.5 for a concrete illustration of how this can happen.

To rephrase our problem another way, by Remark A.9 the simplicial map

$$
\begin{array}{ccc}
\mathcal{T}_{[0,0]} & \overset{\sim}{\longrightarrow} & \mathcal{T} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \overset{\sim}{\longrightarrow} & \mathcal{T}_{[0,0]}
\end{array}
$$

is a homotopy equivalence. The simplicial set without the differentials,

$$
\begin{array}{ccc}
\mathcal{T}_{[0,0]} & \overset{\sim}{\longrightarrow} & \mathcal{T}_{[0,0]} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \overset{\sim}{\longrightarrow} & \mathcal{T}_{[0,0]}
\end{array}
$$

is homotopy equivalent to Quillen’s $Q$-construction. There is a natural map

$$
\begin{array}{ccc}
\mathcal{T}_{[0,0]} & \longrightarrow & \mathcal{T}_{[0,0]} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \longrightarrow & \mathcal{T}_{[0,0]}
\end{array}
$$
which forgets the differential. Since the differential is non-unique, this map is not an isomorphism. This is our problem. What we need to see is that the map forgetting the differentials, although not an isomorphism, is still a homotopy equivalence. Here, fortunately, my old notes are more helpful.

**Remark A.10.** Before we proceed with the notes I wrote years ago, let me make a comment. It is already clear that the simplicial set has a homotopy type independent of the category $\mathcal{T}$, and depending only on the heart $\mathcal{T}_{[0,0]}$. After all, a simplex involves only objects $X_{ij} \in \mathcal{T}_{[0,0]}$, morphisms $X_{ij} \to X_{i'j'}$, and differentials $X_{ij} \to \Sigma X_{i'j'}$, that is extensions of $X_{ij}$ by $X_{i'j'}$. This data is completely determined by the abelian category $\mathcal{T}_{[0,0]}$.

It follows that the homotopy type of the simplicial set depends only on the heart $\mathcal{T}_{[0,0]}$, and therefore agrees, for example, with the homotopy type in the special case $\mathcal{T} = D(\mathcal{T}_{[0,0]})$, that is the derived category of the heart.

We return to the notes. From now through the rest of this Appendix, all simplicial sets will be assumed to come with coherent differentials. When we write the symbol $\uparrow \tikz[baseline=-2pt] { 
\node (t) at (0,0) {$\mathcal{T}_{[0,0]}$}; 
\node (r) at (0,1.5) {$\mathcal{T}$}; 
\draw[->,line width=1.5pt] (t) -- (r); 
\draw[->,line width=1.5pt] (r) -- (t); 
}$, we will really mean what we have, until now, been denoting $\uparrow \tikz[baseline=-2pt] { 
\node (t) at (0,0) {$\mathcal{T}_{[0,0]}$}; 
\node (r) at (0,1.5) {$\mathcal{T}$}; 
\draw[->,line width=1.5pt] (t) -- (r); 
\draw[->,line width=1.5pt] (r) -- (t); 
}$, We will only explicitly write the symbol for the differential in the shorthand for the simplicial set when we want to indicate that the differential is restricted. Thus, the symbol $\uparrow \tikz[baseline=-2pt] { 
\node (t) at (0,0) {$\mathcal{T}_{[0,0]}$}; 
\node (r) at (0,1.5) {$R$}; 
\draw[->,line width=1.5pt] (t) -- (r); 
\draw[->,line width=1.5pt] (r) -- (t); 
}$
will stand for the simplicial subset of \( \mathcal{T}_{[0,0]} \), where the differential yields not any semi–triangles, but distinguished triangles. Since this makes the differentials unique, this simplicial set is isomorphic to the one without the differentials; that is, it is homotopy equivalent to Quillen’s \( Q \)-construction.

We wish to show the inclusion

\[
\begin{array}{ccc}
R & \rightarrow & \mathcal{T}_{[0,0]} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \rightarrow & \mathcal{T}_{[0,0]}
\end{array}
\]

a homotopy equivalence. The idea is to study

\[
\begin{array}{ccc}
R & \rightarrow & \mathcal{T}_{[0,0]} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \rightarrow & \mathcal{T}_{[0,0]}
\end{array}
\]

Recall that this means a simplicial set with differentials, and the differentials in the top square are restricted. The restricted differentials yield distinguished triangles, not only semi–triangles. We have

**Lemma A.11.** *The natural projection*

\[
\begin{array}{ccc}
R & \rightarrow & \mathcal{T}_{[0,0]} \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \rightarrow & \mathcal{T}_{[0,0]}
\end{array}
\]

induces a homotopy equivalence.
Proof. Trivial.  

Lemma A.12. The natural projection

\[
\begin{array}{c}
\xymatrix{ R \ar[r] & \pi \ar[r] & R \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\end{array}
\]

is a quasifibration, having the simplicial set for its homotopy fiber.

Proof. The Segal fiber of the map \( \pi \) is the simplicial set

\[
\begin{array}{c}
\xymatrix{ R \ar[r] & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\mathcal{T}_{[0,0]} \ar[ur] & & \mathcal{T}_{[0,0]} \\
\end{array}
\]

The homotopies
followed by

allow the identity on the Segal fiber to factor through . Then

one easily shows this factorisation is a homotopy equivalence, and that the face maps in $X$ induce homotopy equivalences on the Segal fibers.

Now we want to study the simplicial set that the author finds difficult to write down. By rights, in keeping with our conventions, its symbol should be
In other words, all the differentials are restricted, except the ones involving the line on the left. We have a string of easy lemmas.

**Lemma A.13.** The natural projection

induces a homotopy equivalence.

**Proof.** The Segal fiber is contracted by the homotopy
\textbf{Lemma A.14.} The natural projection

induces a homotopy equivalence.

\textit{Proof.} The Segal fiber is contracted by the homotopy
Lemma A.15. The simplicial set $\mathcal{T}_{[0,0]}$ is contractible.

Proof. Trivial. \hfill $\square$

Lemmas A.13, A.14 and A.15 combine to show that the simplicial set

is contractible. It therefore suffices to show that the natural projection

\[ \phi \]
induces a homotopy equivalence. After all, it is a map from a contractible set to the homotopy fiber we want to show contractible.

So we will now proceed to study the Segal fiber of the map $\phi$. The Segal fiber is the simplicial set

\[
\begin{array}{ccc}
R & \rightarrow & R \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \rightarrow & \mathcal{T}_{[0,0]} \\
\downarrow & & \downarrow \\
W & \rightarrow & W
\end{array}
\]

Now, the homotopy

\[
\begin{array}{ccc}
R & \rightarrow & R \\
\uparrow & & \uparrow \\
\mathcal{T}_{[0,0]} & \rightarrow & \mathcal{T}_{[0,0]} \\
\downarrow & & \downarrow \\
W & \rightarrow & W
\end{array}
\]

may be followed by a homotopy
and the point is that the two homotopies combine to factor the identity on the Segal fiber of $\phi$ through a space that depends little on the fixed data.

The fixed data in particular gives us a $(0,1)$-cell

\[
\begin{align*}
X_{NW} & \to X_{NE} \\
W_{W} & \to W_{E}
\end{align*}
\]
The identity on the Segal fiber of \( \phi \) factors, up to homotopy, through a simplicial set we will denote

\[
\begin{pmatrix}
X_{NW} & \to & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \to & W_E
\end{pmatrix}
\to
\begin{pmatrix}
R \\
\uparrow \\
\uparrow \\
T_{[0,0]} & \to & T_{[0,0]} \\
\uparrow \\
\uparrow \\
\uparrow \\
0 & \to & R
\end{pmatrix}
\]

and I owe the reader a definition of what this means.

A simplex in

is a diagram

\[
\begin{array}{ccccccc}
V_{p0} & \to & \cdots & \to & V_{pq} & \to & Y_p \\
\uparrow & & & & \uparrow & & \\
& & & & \vdots & & \\
& & & & \uparrow & & \\
& & & & \vdots & & \\
& & & & \uparrow & \cdots & \\
V_{00} & \to & \cdots & \to & V_{0q} & \to & Y_0 \\
\uparrow & & \cdots & & \uparrow & & \\
& & & & \vdots & & \\
& & & & \uparrow & \cdots & \\
U_0 & \to & \cdots & \to & U_q & \to & 0
\end{array}
\]
together with differentials satisfying some conditions. A simplex in the more complicated simplicial set

\[
\begin{pmatrix}
X_{NW} ightarrow X_{NE} \\
W_W ightarrow W_E
\end{pmatrix}
\rightarrow
\begin{pmatrix}
R \\
T_{[0,0]} \\
T_{[0,0]} \\
0
\end{pmatrix}
\]

is a diagram

\[
\begin{align*}
V_{p0} & \rightarrow \cdots \rightarrow V_{pq} \rightarrow Y_p \\
& \uparrow \\
& \vdots \\
& \uparrow \\
V_{00} & \rightarrow \cdots \rightarrow V_{0q} \rightarrow Y_0 \\
& \uparrow \\
U_0 & \rightarrow \cdots \rightarrow U_q \rightarrow 0
\end{align*}
\]

as above, together with a map into it from

\[
\begin{pmatrix}
X_{NW} ightarrow X_{NE} \\
W_W ightarrow W_E
\end{pmatrix}
\]

This means the following. For each \( U_i \), we have a map \( X_{NE} \rightarrow \Sigma U_i \). For each \( V_{ij} \), we have a map \( W_W \rightarrow V_{ij} \). For each \( Y_i \), we have a map \( X_{NW} \rightarrow Y_i \). If we define the map
\( W_E \rightarrow Y_i \) to be zero, this gives maps

\[
\begin{pmatrix}
X_{NW} & \rightarrow & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \rightarrow & W_E
\end{pmatrix}
\rightarrow
\begin{pmatrix}
R \\
\uparrow \quad \uparrow \\
T_{[0,0]} & \rightarrow & T_{[0,0]} \\
\downarrow \quad \downarrow \\
T_{[0,0]} & \rightarrow & 0 \\
\downarrow \quad \downarrow \\
R
\end{pmatrix}
\]

and we require that they commute with all the structure maps. The reader is asked to verify that the identity on the Segal fiber factors up to homotopy as we said.

It suffices therefore to prove the contractibility of the simplicial set

\[
\begin{pmatrix}
X_{NW} & \rightarrow & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \rightarrow & W_E
\end{pmatrix}
\rightarrow
\begin{pmatrix}
R \\
\uparrow \quad \uparrow \\
T_{[0,0]} & \rightarrow & T_{[0,0]} \\
\downarrow \quad \downarrow \\
T_{[0,0]} & \rightarrow & 0 \\
\downarrow \quad \downarrow \\
R
\end{pmatrix}
\]

The next point is to reduce to the contractibility in the special case where the simplex

\[
\begin{pmatrix}
X_{NW} & \rightarrow & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \rightarrow & W_E
\end{pmatrix}
\]
vanishes. The argument is as in the proof of Lemma 7.11. The simplicial set

\[
\begin{pmatrix}
X_{NW} \rightarrow X_{NE} \\
W_W \rightarrow W_E
\end{pmatrix}
\rightarrow
\begin{pmatrix}
R \\
\tau_{[0,0]} \\
\tau_{[0,0]}
\end{pmatrix}
\]

has a fake \(H\)-space action, as well as an action by the true \(H\)-space

\[
\begin{pmatrix}
0 \rightarrow 0 \\
0 \rightarrow 0
\end{pmatrix}
\rightarrow
\begin{pmatrix}
R \\
\tau_{[0,0]} \\
\tau_{[0,0]}
\end{pmatrix}
\]

Playing off the two actions exactly as in the proof of Lemma 7.11, one proves that the contractibility of the simplicial set
implies that

\[
\begin{pmatrix}
X_{NW} & \to & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \to & W_E
\end{pmatrix}
\to
\begin{pmatrix}
R & \\
\uparrow & \uparrow & \uparrow \\
\uparrow & \uparrow & \uparrow \\
0 & \to & 0
\end{pmatrix}
\]

are also contractible.

**Remark A.16.** We actually want a slight refinement of the argument of Lemma 7.11. We want the sharper statement that if

\[
\begin{pmatrix}
0 & \to & 0 \\
\uparrow & & \uparrow \\
0 & \to & 0
\end{pmatrix}
\to
\begin{pmatrix}
R & \\
\uparrow & \uparrow & \uparrow \\
\uparrow & \uparrow & \uparrow \\
0 & \to & 0
\end{pmatrix}
\]

is \(n\)-connected, so is

\[
\begin{pmatrix}
X_{NW} & \to & X_{NE} \\
\uparrow & & \uparrow \\
W_W & \to & W_E
\end{pmatrix}
\to
\begin{pmatrix}
R & \\
\uparrow & \uparrow & \uparrow \\
\uparrow & \uparrow & \uparrow \\
0 & \to & 0
\end{pmatrix}
\]

In this case, it would follow that the Segal fibers are all \(n\)-connected, and the homotopy sequence then implies that the simplicial set
is \((n+1)\)-connected.

In other words, if we could show that the natural inclusion

is a homotopy equivalence, we would be done. By Remark A.16 we know that if

is \(n\)-connected, then

is \((n+1)\)-connected. If the inclusion is a homotopy equivalence, then both sets are contractible.

**Remark A.17.** This is where my notes stop. I have no recollection what idea, if any, I had for proving the inclusion.
a homotopy equivalence. Let me make the following observation. In both simplicial
sets, a 0-simplex is nothing other than a semi-triangle; it is a simplex

\[ V \longrightarrow Y \]

\[ U \longrightarrow 0 \]

in other words a semi-triangle

\[ U \longrightarrow V \longrightarrow Y \longrightarrow \Sigma U. \]

The higher-order simplices are morphisms of semi-triangles, with the restriction that
some induced semi-triangles be true triangles. If one takes an edgewise subdivision,
then these simplicial sets are actually nerves of categories. I don’t know whether this
helps.
