Abstract

We compute the group homology, the topological $K$-theory of the reduced $C^*$-algebra and the algebraic $K$- and $L$-theory of the group ring of the semi-direct product of the three-dimensional discrete Heisenberg group by $\mathbb{Z}/4$. These computations will follow from the more general treatment of a certain class of groups $G$ which occur as extensions $1 \to K \to G \to Q \to 1$ of a torsionfree group $K$ by a group $Q$ which satisfies certain assumptions. The key ingredients are the Baum-Connes and Farrell-Jones Conjectures and methods from equivariant algebraic topology.

Key words: $K$- and $L$-groups of group rings and group $C^*$-algebras, three-dimensional Heisenberg group.

0 Introduction

The original motivation for this paper was the question of Chris Phillips how the topological $K$-theory of the reduced (complex) $C^*$-algebra of the semi-direct
The answer, which is proved in Theorem 2.6, consists of an explicit isomorphism

\[ j_0 \bigoplus c[0] \bigoplus c[2] : K_0(\{\ast\}) \bigoplus \tilde{R}_C(Z/4) \bigoplus \tilde{R}_C(Z/2) \cong K_0(C^*_r(\text{Hei} \times Z/4)) \]

and a short exact sequence

\[ 0 \rightarrow \tilde{R}_C(Z/4) \bigoplus \tilde{R}_C(Z/2) \xrightarrow{\phi[0]} K_1(C^*_r(\text{Hei} \times Z/4)) \xrightarrow{\sigma} \tilde{K}_1(S^3) \rightarrow 0, \]

which splits since \( \tilde{K}_1(S^3) \cong Z \). Here \( \tilde{R}_C(Z/m) \) is the kernel of the split surjective map \( R_C(Z/m) \rightarrow R_C(\{1\}) \cong Z \) which sends the class of a complex \( Z/m \)-representation to the class of \( C \otimes_{C[Z/m]} V \). As abelian group we get for \( n \in Z \)

\[ K_n(C^*_r(\text{Hei} \times Z/4)) \cong Z^5. \]

This computation will pay a role in the paper by Lück, Phillips and Walters [20], where certain \( C^* \)-algebras given by semi-direct products of rotation algebras with finite cyclic groups are classified.

Although the group \( \text{Hei} \times Z/4 \) is very explicit, this computation is highly non-trivial and requires besides the Baum-Connes Conjecture a lot of machinery from equivariant algebraic topology. Even harder is the computation of the middle and lower K-theory. The result is (see Corollary 3.9)

\[ \text{Wh}_n(\text{Hei} \times Z/4) \cong \begin{cases} NK_n(Z[Z/4]) \oplus NK_n(Z[Z/4]) & \text{for } n = 0, 1; \\ 0 & \text{for } n \leq -1, \end{cases} \]

where \( NK_n(Z[Z/4]) \) denotes the \( n \)-th Nil-group of \( Z[Z/4] \) which appears in the Bass-Heller-Swan decomposition of \( Z[Z/4 \times Z] \). So the lower \( K \)-theory is trivial and the middle \( K \)-theory is completely made up of Nil-groups.

We also treat the \( L \)-groups. The answer and calculation is rather messy due to the appearance of UNil-terms and the structure of the family of infinite virtually cyclic subgroups (see Theorem 4.11). If one is willing to invert 2, these UNil-terms and questions about decorations disappear and the answer is given by the short split exact sequence

\[ 0 \rightarrow L_n(Z) \left[ \frac{1}{2} \right] \bigoplus \tilde{L}_n(Z[Z/2]) \left[ \frac{1}{2} \right] \bigoplus \tilde{L}_{n-1}(Z[Z/2]) \left[ \frac{1}{2} \right] \bigoplus \tilde{L}_n(Z[Z/4]) \left[ \frac{1}{2} \right] \bigoplus \tilde{L}_{n-1}(Z[Z/4]) \left[ \frac{1}{2} \right] \bigoplus \tilde{L}_n(Z[\text{Hei} \times Z/4]) \left[ \frac{1}{2} \right] \rightarrow L_{n-3}(Z) \left[ \frac{1}{2} \right] \rightarrow 0. \]
Finally we will also compute the group homology (see Theorem 5.6)

\[
H_n(G) = \begin{cases} 
\mathbb{Z}/2 \times \mathbb{Z}/4 & \text{for } n \geq 1, n \neq 2, 3; \\
\mathbb{Z}/2 & n = 2; \\
\mathbb{Z} \times \mathbb{Z}/2 \times \mathbb{Z}/4 & n \geq 3.
\end{cases}
\]

In turns out that we can handle a much more general setting. Namely, we will consider an extension of (discrete) groups

\[
1 \rightarrow K \xrightarrow{i} G \xrightarrow{q} Q \rightarrow 1
\]

which satisfies the following conditions:

(M) Each non-trivial finite subgroup of \(Q\) is contained in a unique maximal finite subgroup;

(NM) Let \(M\) be a maximal finite subgroup of \(Q\). Then \(N_Q M = M\) unless \(G\) is torsionfree;

(T) \(K\) is torsionfree.

The special case, where \(K\) is trivial, is treated in [11, Theorem 5.1]. In [11, page 101] it is explained using [22, Lemma 4.5], [22, Lemma 6.3] and [23, Propositions 5.17, 5.18 and 5.19 in II.5 on pages 107 and 108] why the following groups satisfy conditions (M) and (NM):

- Extensions \(1 \rightarrow \mathbb{Z}^n \rightarrow Q \rightarrow F \rightarrow 1\) for finite \(F\) such that the conjugation action of \(F\) on \(\mathbb{Z}^n\) is free outside \(0 \in \mathbb{Z}^n\);
- Fuchsian groups;
- One-relator groups.

Of course \(\text{Hei} \times \mathbb{Z}/4\) is an example for \(G\). For such groups \(G\) we will establish certain exact Mayer-Vietoris sequences relating the \(K\)- or \(L\)-theory of \(G\) to the \(K\)- and \(L\)-theory of \(p^{-1}(M)\) for maximal finite subgroups \(M \subseteq Q\) and terms involving the quotients \(G/E_G\) and \(p^{-1}(M)/E_{p^{-1}(M)}\). The classifying space \(EG\) for proper \(G\)-actions plays an important role and often there are nice small geometric models for them. One key ingredient in the computations for \(\text{Hei} \times \mathbb{Z}/4\) will be to figure out that \(G/E_G\) is in this case \(S^3\). For instance the computation of the group homology illustrates that it is often very convenient to work with these spaces \(G/E_G\) although one wants information about \(BG\).

1 Topological \(K\)-theory

For a \(G\)-\(CW\)-complex \(X\) let \(K^G_\ast (X)\) be its equivariant \(K\)-homology theory. If \(G\) is trivial, we abbreviate \(K_\ast (X)\). For a \(C^*\)-algebra \(A\) let \(K_\ast (A)\) be its topological \(K\)-theory. Recall that a model \(EG\) for the classifying space for proper \(G\)-actions

\[
\ldots
\]

\[
\ldots
\]
is a $G$-CW-complex with finite isotropy groups such that $(EG)^H$ is contractible for each finite subgroup $H \subseteq G$. It has the property that for any $G$-CW-complex $X$ with finite isotropy groups there is up to $G$-homotopy precisely one $G$-map from $X$ to $EG$. In particular two models for $EG$ are $G$-homotopy equivalent. For more information about these spaces $EG$ we refer for instance to [6], [19], [24], [30]. Recall that the Baum-Connes Conjecture (see [6, Conjecture 3.15 on page 254]) says that the assembly map

$$\text{asmb}: K^G_n(EG) \cong K_n(C^*_r(G))$$

is an isomorphism for each $n \in \mathbb{Z}$, where $C^*_r(G)$ is the reduced group $C^*$-algebra associated to $G$. Let $EG$ be a model for the classifying space for free $G$-actions, i.e. a free $G$-CW-complex which is contractible (after forgetting the group action). Up to $G$-homotopy there is precisely one $G$-map $s: EG \to EG$. The classical assembly map $a$ is defined as the composition

$$a: K_n(BG) = K^G_n(EG) \xrightarrow{K^G_n([s])} K^G_n(EG) \xrightarrow{\text{asmb}} K_n(C^*_r(G)).$$

For more information about the Baum-Connes Conjecture we refer for instance to [6], [21], [24], [31].

From now on consider a group $G$ as described in (0.1). We want to compute $K^G_n(EG)$ which is by the Baum-Connes Conjecture the same as $K_n(C^*_r(G))$.

First we construct a nice model for $EQ$. Let $\{(M_i) \mid i \in I\}$ be the set of conjugacy classes of maximal finite subgroups of $M_i \subseteq Q$. By attaching free $Q$-cells we get an inclusion of $Q$-CW-complexes $j_i: \coprod_{i \in I} Q \times M_i \to EQ$. Define $EQ$ as the $Q$-pushout

$$\coprod_{i \in I} Q \times M_i \xrightarrow{u_i} \coprod_{i \in I} Q / M_i \xrightarrow{j_i} EQ$$

where $u_i$ is the obvious $Q$-map obtained by collapsing each $EM_i$ to a point.

We have to explain why $EQ$ is a model for the classifying space for proper actions of $Q$. Obviously it is a $Q$-CW-complex. Its isotropy groups are all finite. We have to show for $H \subseteq Q$ finite that $(EQ)^H$ contractible. We begin with the case $H \neq \{1\}$. Because of conditions (M) and (NM) there is precisely one index $i_0 \in I$ such that $H$ is subconjugated to $M_{i_0}$ and is not subconjugated to $M_i$ for $i \neq i_0$ and we get

$$\left(\coprod_{i \in I} Q / M_i\right)^H = (Q / M_{i_0})^H = \{\ast\}.$$
Let $X$ be a $Q$-CW-complex and $Y$ be a $G$-CW-complex. Then $X \times Y$ with the $G$-action given by $g \cdot (x, y) = (p(g)x, gy)$ is a $G$-CW-complex and the $G$-isotropy group $G_{(x, y)}$ of $(x, y)$ is $p^{-1}(H_x) \cap G_y$. Hence $EQ \times EG$ is a $G$-CW-model for $EG$ and $EQ \times EG$ is a $G$-CW-model for $EG$, since $\ker(p: G \to Q)$ is torsionfree by assumption. Let $Z$ be a $M_l$-CW-complex. Then there is a $G$-homeomorphism

$$G \times p^{-1}(M_l) \left(Z \times \text{res}_G^{p^{-1}(M_l)} Y\right) \xrightarrow{\cong} (Q \times M_l) \times Y \quad (g, (z, y)) \mapsto ((p(g), z), gy).$$

The inverse sends $((q, z), y)$ to $(g, (z, g^{-1}y)$ for any choice of $g \in G$ with $p(g) = q$.

If we cross the $Q$-pushout (1.1) with $EG$, then we obtain the following $G$-pushout

$$\coprod_{i \in I} G \times p^{-1}(M_i) \xrightarrow{j_2} \coprod_{i \in I} G \times p^{-1}(M_i) \xrightarrow{k_2} EG \quad (1.2)$$

If we divide out the $G$-action in the pushout (1.2) above we obtain the pushout

$$\coprod_{i \in I} Bp^{-1}(M_i) \xrightarrow{j_3} \coprod_{i \in I} Bp^{-1}(M_i) \xrightarrow{k_3} G\backslash EG \quad (1.3)$$

If we divide out the $Q$-action in the pushout (1.1) we obtain the pushout

$$\coprod_{i \in I} BM_i \xrightarrow{j_4} \coprod_{i \in I} BM_i \xrightarrow{k_4} Q\backslash EQ \quad (1.4)$$

**Theorem 1.5.** Let $G$ be the group appearing in (0.1) and assume that conditions $(M)$, $(NM)$ and $(T)$ hold. Assume that $G$ and all groups $p^{-1}(M_i)$ satisfy the Baum-Connes Conjecture. Then the Mayer-Vietoris sequence associated to (1.2) yields the long exact sequence of abelian groups
\[
\ldots \xrightarrow{\partial_{n+1}} \bigoplus_{i \in I} K_n(Bp^{-1}(M_i)) \\
(\oplus_{i \in I} K_n(B^{l(i)}) \oplus \oplus_{i \in I} a[i]_{+}) \rightarrow K_n(BG) \bigoplus \left( \bigoplus_{i \in I} K_n(C_{r}^{*}(p^{-1}(M_i))) \right) \\
(\oplus_{i \in I} K_n(C_{r}^{*}(G))) \xrightarrow{\partial_n} \bigoplus_{i \in I} K_m-1(Bp^{-1}(M_i)) \\
(\oplus_{i \in I} K_n-(B^{l(i)}) \oplus \oplus_{i \in I} a[i]_{-}) \rightarrow K_{n-1}(BG) \bigoplus \left( \bigoplus_{i \in I} K_{n-1}(C_{r}^{*}(p^{-1}(M_i))) \right) \\
(\oplus_{i \in I} K_{n-1}(C_{r}^{*}(G))) \xrightarrow{\partial_{n-1}} \bigoplus_{i \in I} K_{m-2}(Bp^{-1}(M_i)) \\
\ldots
\]

Here the maps a[i]_{+} and a are classical assembly maps and l_{i} : p^{-1}(M_{i}) \to G is the inclusion.

Let \Lambda be a ring with \mathbb{Z} \subseteq \Lambda \subseteq \mathbb{Q} such that the order of each finite subgroup of G is invertible in \Lambda. Then the composition

\[
\Lambda \otimes_{\mathbb{Z}} K_{n}(Bp^{-1}(M_{i})) \xrightarrow{id_{\Lambda} \otimes \text{ind}^{(1)}} K_{n}(C_{r}^{*}(p^{-1}(M_{i}))) = K_{n}^{p^{-1}(M_{i})}(E^{p^{-1}(M_{i})}) \\
\xrightarrow{id_{\Lambda} \otimes \text{ind}^{(1)}} \Lambda \otimes_{\mathbb{Z}} K_{n}(p^{-1}(M_{i}) \backslash E^{p^{-1}(M_{i})})
\]

is an isomorphism, where ind denotes the induction map. In particular the long exact sequence above reduces after applying \Lambda \otimes_{\mathbb{Z}} to split exact short exact sequences of \Lambda-modules

\[
0 \rightarrow \bigoplus_{i \in I} \Lambda \otimes_{\mathbb{Z}} K_{n}(Bp^{-1}(M_{i})) \left( \oplus_{i \in I} \text{id}_{\Lambda} \otimes K_{n}(B^{l(i)}) \oplus \oplus_{i \in I} \text{id}_{\Lambda} \otimes a[i]_{+} \right) \\
\Lambda \otimes_{\mathbb{Z}} K_{n}(BG) \bigoplus \left( \bigoplus_{i \in I} \Lambda \otimes_{\mathbb{Z}} K_{n}(C_{r}^{*}(p^{-1}(M_{i}))) \right) \\
\oplus_{i \in I} \text{id}_{\Lambda} \otimes K_{n}(C_{r}^{*}(G)) \xrightarrow{\partial_{n-1}} \Lambda \otimes_{\mathbb{Z}} K_{n}(C_{r}^{*}(G)) \rightarrow 0.
\]

**Proof.** The Mayer Vietoris sequence is obvious using the fact that for a free G-CW-complex X there is a canonical isomorphism \( K_{n}^{G}(X) \xrightarrow{\cong} K_{n}(G \backslash X) \). The composition

\[
\Lambda \otimes_{\mathbb{Z}} K_{n}(Bp^{-1}(M_{i})) \xrightarrow{id_{\Lambda} \otimes \text{ind}^{(1)}} K_{n}(C_{r}^{*}(p^{-1}(M_{i}))) = K_{n}^{t^{-1}(M_{i})}(E^{p^{-1}(M_{i})}) \\
\xrightarrow{id_{\Lambda} \otimes \text{ind}^{(1)}} \Lambda \otimes_{\mathbb{Z}} K_{n}(p^{-1}(M_{i}) \backslash E^{p^{-1}(M_{i})})
\]

is bijective by [22, Lemma 2.8 (a)]. \( \Box \)
The advantage of the following version is that it involves instead of the spaces $BG$ the spaces $G\setminus EG$ which often have rather small geometric models. In the case $G = \text{He} \times \mathbb{Z}/4$ we will see that $G\setminus EG$ is the three-dimensional sphere $S^3$ (see Lemma 2.4).

**Theorem 1.6.** Let $G$ be the group appearing in (0.1) and assume conditions (M), (NM) and (T) hold. Assume that $G$ and all groups $p^{-1}(M_i)$ satisfy the Baum-Connes Conjecture. Then there is a long exact sequence of abelian groups

$$
\cdots \to c_{n+1} \bigoplus_{i \in I} d[i]_{n+1} \to K_{n+1}(G\setminus EG) \xrightarrow{\partial_{n+1}} \bigoplus_{i \in I} K_n(C^*_r(p^{-1}(M_i)))
$$

$$
(\bigoplus_{i \in I} K_n(C^*_r(|l_i|))) \oplus (\bigoplus_{i \in I} c[i]) \to K_n(C^*_r(G)) \bigoplus \left( \bigoplus_{i \in I} K_n(p^{-1}(M_i)\setminus E_{p^{-1}}(M_i)) \right)
$$

$$
c_n \bigoplus_{i \in I} d[i] \to K_n(G\setminus EG) \xrightarrow{\partial_n} \bigoplus_{i \in I} K_{n-1}(C^*_r(p^{-1}(M_i)))
$$

Here the homomorphisms $d[i]_{n}$ come from the up to equivariant homotopy unique $(p^{-1}(M_i) \to G)$-equivariant maps $E_{p^{-1}}(M_i) \to EG$. The maps $c_n$ and (analogously for $c[i]$) are the compositions

$$
K_n(C^*_r(G)) \xrightarrow{\text{emb}^{-1}} K_n^G(EG) \xrightarrow{\text{ind}_{G^{-1(1)}}} K_n(G\setminus EG).
$$

Let $\Lambda$ be a ring with $\mathbb{Z} \subseteq \Lambda \subseteq \mathbb{Q}$ such that the order of each finite subgroup of $G$ is invertible in $\Lambda$. Then the composition

$$
\Lambda \boxtimes_{\mathbb{Z}} K_n(BG) \xrightarrow{\text{id}_\Lambda \boxtimes c_n} \Lambda \boxtimes_{\mathbb{Z}} K_n(C^*_r(G)) \xrightarrow{\text{id}_\Lambda \boxtimes c_n} \Lambda \boxtimes_{\mathbb{Z}} K_n(G\setminus EG)
$$

is an isomorphism of $\Lambda$-modules. In particular the long exact sequence above reduces after applying $\Lambda \boxtimes_{\mathbb{Z}} -$ to split exact short sequences of $\Lambda$-modules

$$
0 \to \bigoplus_{i \in I} \Lambda \boxtimes_{\mathbb{Z}} K_n(p^{-1}(M_i))) \xrightarrow{(\bigoplus_{i \in I} \text{id}_\Lambda \boxtimes K_n(C^*_r(|l_i|))^\oplus (\bigoplus_{i \in I} \text{id}_\Lambda \boxtimes c[i])} \\
\Lambda \boxtimes_{\mathbb{Z}} K_n(C^*_r(G)) \bigoplus \left( \bigoplus_{i \in I} \Lambda \boxtimes_{\mathbb{Z}} K_n(p^{-1}(M_i)\setminus E_{p^{-1}}(M_i)) \right) \\
\xrightarrow{\text{id}_\Lambda \boxtimes c_n \oplus \bigoplus_{i \in I} \text{id}_\Lambda \boxtimes d[i]} \Lambda \boxtimes_{\mathbb{Z}} K_n(G\setminus EG) \to 0.
$$

**Proof.** We get from the pushout (1.3) the long exact Mayer Vietoris sequence
for (non-equivariant) topological $K$-theory

\[ \ldots \xrightarrow{\partial_{n+1}} \bigoplus_{i \in I} K_n(Bp^{-1}(M_i)) \xrightarrow{\bigoplus_{i \in I} K_n(Bl_i)} \bigoplus_{i \in I} K_n(p^{-1}(M_i) \setminus s_i) \]

\[ K_n(BG) \xrightarrow{\bigoplus_{i \in I} K_n(p^{-1}(M_i) \setminus E_p^{-1}(M_i))} \xrightarrow{H_n(G,s)} \bigoplus_{i \in I} K_n(p^{-1}(M_i) \setminus s_i) \xrightarrow{K_{n-1}(G\setminus s) \bigoplus (\bigoplus_{i \in I} d[i])} K_{n-1}(BG) \]

where $s_i: E_p^{-1}(M_i) \to E_p^{-1}(M_i)$ and $s: EG \to EG$ are the (up to equivariant homotopy unique) equivariant maps. Now one splices the long exact Mayer-Vietoris sequences from above and from Theorem 1.5 together. \qed

2 The semi-direct product of the Heisenberg group and a cyclic group of order four

We want to study the following example. Let $\text{Hei}$ be the discrete Heisenberg group. We will use the presentation

\[ \text{Hei} = \langle u, v, z \mid [u, z] = 1, [v, z] = 1, [u, v] = z \rangle. \] (2.1)

Throughout this section let $G$ be the semi-direct product

\[ G = \text{Hei} \rtimes \mathbb{Z}/4 \]

with respect to the homomorphism $\mathbb{Z}/4 \to \text{aut}(\text{Hei})$ which sends the generator $t$ of $\mathbb{Z}/4$ to the automorphism of $\text{Hei}$ given on generators by $z \mapsto z$, $u \mapsto v$ and $v \mapsto u^{-1}$. Let $Q$ be the semi-direct product $\mathbb{Z}^2 \rtimes \mathbb{Z}/4$ with respect to the automorphism $\mathbb{Z}^2 \to \mathbb{Z}^2$ which comes from multiplication with the complex number $i$ and the inclusion $\mathbb{Z}^2 \subseteq \mathbb{C}$. Since the action of $\mathbb{Z}/4$ on $\mathbb{Z}^2$ is free outside $0$, the group $Q$ satisfies (M) and (NM) (see [22, Lemma 6.3]). The group $G$ has the presentation

\[ G = \langle u, v, z, t \mid [u, z] = [v, z] = [t, z] = t^4 = 1, [u, v] = z, tu^{-1} = v, vtu^{-1} = u^{-1} \rangle. \]

Let $i: \mathbb{Z} \to G$ be the inclusion sending the generator of $\mathbb{Z}$ to $z$. Let $p: G \to Q$ be the group homomorphism, which sends $z$ to the unit element, $u$ to $(1, 0)$ in $\mathbb{Z}^2 \subseteq Q$, $v$ to $(0, 1)$ in $\mathbb{Z}^2 \subseteq Q$ and $t$ to the generator of $\mathbb{Z}/4 \subseteq Q$. Then $1 \to \mathbb{Z} \to G \to Q \to 1$ is a central extension which satisfies the conditions (M), (NM) and (T) appearing in (0.1). Moreover, $G$ is amenable and hence $G$ and all its subgroups satisfy the Baum-Connes Conjecture [15].
In order to apply the general results above we have to figure out the conjugacy classes of finite subgroups of \(Q = \mathbb{Z}^2 \times \mathbb{Z}/4\) and among them the maximal ones. An element of order 2 in \(Q\) must have the form \(xt^2\) for \(x \in \mathbb{Z}^2\). In the sequel we write the group multiplication in \(Q\) and \(G\) multiplicatively and in \(\mathbb{Z}^2\) additively. We compute \((xt^2)^2 = xt^2 xt^2 = (x - x) = 0\). Hence the set of elements of order two in \(Q\) is \(\{xt^2 \mid x \in \mathbb{Z}^2\}\). Consider \(e_1 = (1, 0)\) and \(e_2 = (0, 1)\) in \(\mathbb{Z}^2\). We claim that up to conjugacy there are the following subgroups of order two: \(\langle e_1 t^2 \rangle, \langle e_1 e_2 t^2 \rangle, \langle t^2 \rangle\). This follows from the computations for \(x, y \in \mathbb{Z}^2\)

\[
y(xt^2)y^{-1} = yxyt^2 = (x + 2y)t^2; \\
t(xt^2)t^{-1} = txt^{-1}t^2 = (ix)t^2.
\]

An element of order 4 must have the form \(xt\) for \(x \in \mathbb{Z}^2\). We compute

\[
(xt)^4 = xtxt^{-1}t^2xt^{-2}t^3xt^{-3} = (x + ix + i^2x + i^3x) = (1 + i + i^2 + i^3)x = 0x = 0.
\]

Hence the set of elements of order four in \(Q\) is \(\{xt \mid x \in \mathbb{Z}^2\}\). We claim that up to conjugacy there are the following subgroups of order four: \(\langle e_1 t \rangle, \langle t \rangle\). This follows from the computations for \(x, y \in \mathbb{Z}^2\)

\[
y(xt)y^{-1} = (x + y - iy)t; \\
t(xt)t^{-1} = (ix)t.
\]

We have \((e_1 t)^2 = e_1 te_1 t = e_1 ie_1 t^2 = e_1 e_2 t^2\). The considerations above imply

**Lemma 2.2.** Up to conjugacy \(Q\) has the following non-trivial finite subgroups

\[
\langle e_1 t^2 \rangle, \langle e_1 e_2 t^2 \rangle, \langle t^2 \rangle, \langle e_1 t \rangle, \langle t \rangle.
\]

The maximal finite subgroups are up to conjugacy

\[
M_0 = \langle t \rangle, M_1 = \langle e_1 t \rangle, M_2 = \langle e_1 t^2 \rangle.
\]

Since \(t^4 = 1\), \((ut^2)^2 = ut^2 ut^{-2} = uu^{-1} = 1\) and \((ut)^4 = utut^{-1}t^2ut^{-2}t^3ut^{-3} = uu^{-1}u^{-1} = z\) hold in \(G\), the preimages of these groups under \(p: G \rightarrow Q\) are given by

\[
p^{-1}(M_0) = \langle t, z \rangle \cong \mathbb{Z}/4 \times \mathbb{Z}; \\
p^{-1}(M_1) = \langle ut, z \rangle = \langle ut \rangle \cong \mathbb{Z}; \\
p^{-1}(M_2) = \langle ut^2, z \rangle \cong \mathbb{Z}/2 \times \mathbb{Z}.
\]

On easily checks

**Lemma 2.3.** Up to conjugacy the finite subgroups of \(G\) are \(\langle t \rangle, \langle t^2 \rangle\) and \(\langle ut^2 \rangle\).

Next we construct nice geometric models for \(E_G\) and its orbit space \(\mathbb{E}_G\). Let \(\text{Hei}(\mathbb{R})\) be the real Heisenberg group, i.e. the Lie group of real \((3, 3)\)-matrices of the special form

\[
\begin{pmatrix}
1 & x & y \\
0 & 1 & z \\
0 & 0 & 1
\end{pmatrix}.
\]

In the sequel we identify such a matrix with the element \((x, y, z) \in \mathbb{R}^3\). Thus \(\text{Hei}(\mathbb{R})\) can be identified with the Lie group whose underlying manifold is \(\mathbb{R}^3\) and whose group multiplication is given by

\[(a, b, c) \cdot (x, y, z) = (a + x, b + y + az, c + z).\]

The discrete Heisenberg group is given by the subgroup where all the entries \(x, y, z\) are integers. In the presentation of the discrete Heisenberg group (2.1) the elements \(u, v\) and \(z\) correspond to \((1,0,0), (0,0,1)\) and \((0,1,0)\). Obviously \(\text{Hei}(\mathbb{R})\) is a torsionfree discrete subgroup of the contractible Lie group \(\text{Hei}(\mathbb{R})\). Hence \(\text{Hei}(\mathbb{R})\) is a model for \(E\text{Hei}\) and \(\text{Hei} \setminus \text{Hei}(\mathbb{R})\) for \(B\text{Hei}\). We have the following \(\mathbb{Z}/4\)-action on \(\text{Hei}(\mathbb{R})\), where the generator \(t\) acts by \((x, y, z) \mapsto (-z, y - xz, x)\).

This is an action by automorphisms of Lie groups and induces on \(\text{Hei}\) the homeomorphism \(\mathbb{Z}/4 \to \text{aut}(\text{Hei})\) which we have used above to define \(G = \text{Hei} \times \mathbb{Z}/4\). The \(\text{Hei}\)-action and \(\mathbb{Z}/4\)-action on \(\text{Hei}(\mathbb{R})\) above fit together to give \(G = \text{Hei} \times \mathbb{Z}/4\)-action. The next result is the main geometric input for the desired computations.

**Lemma 2.4.** The manifold \(\text{Hei}(\mathbb{R})\) with the \(G\)-action above is a model for \(\mathbb{E}G\). The quotient space \(G \setminus \mathbb{E}G\) is homeomorphic to \(S^3\).

**Proof.** Let \(\mathbb{R} \subset \text{Hei}(\mathbb{R})\) be the subgroup of elements \(\{(0,y,0) \mid y \in \mathbb{R}\}\). This is the center of \(\text{Hei}(\mathbb{R})\). The intersection \(\mathbb{R} \cap \text{Hei}\) is \(\mathbb{Z} \subset \mathbb{R}\). Thus we get a \(\mathbb{R}/\mathbb{Z} = S^1\)-action on \(\text{Hei} \setminus \text{Hei}(\mathbb{R})\). One easily checks that this \(S^1\)-action and the \(\mathbb{Z}/4\)-action above commute so that we see a \(S^1 \times \mathbb{Z}/4\)-action on \(\text{Hei} \setminus \text{Hei}(\mathbb{R})\). The \(S^1\)-action is free, but the \(S^1 \times \mathbb{Z}/4\)-action is not. Next we figure out its fixed points.

Obviously \(t^2\) sends \((x, y, z)\) to \((-x, y, -z)\). We compute for \((a,b,c) \in \text{Hei}, u \in \mathbb{R}\) and \((x, y, z) \in \text{Hei}(\mathbb{R})\)

\[
(a,b,c) \cdot (0, u, 0) \cdot t \cdot (x, y, z) = (a - z, u + b + y - xz - ax, c + x);
(a,b,c) \cdot (0, u, 0) \cdot t^2 \cdot (x, y, z) = (a - x, u + b + y - az, c - z);
(a,b,c) \cdot (0, u, 0) \cdot (x, y, z) = (a + x, u + b + y + az, c + z).
\]

Hence the isotropy group of \(\text{Hei} \cdot (x, y, z) \in \text{Hei} \setminus \text{Hei}(\mathbb{R})\) under the \(S^1 \times \mathbb{Z}/4\)-action contains \((\exp(2\pi i u), t)\) in its isotropy group under the \(S^1 \times \mathbb{Z}/4\)-action if and only if \((a - z, u + b + y - xz - ax, c + x) = (x, y, z)\) holds for some integers \(a, b, c\). The last statement is equivalent to the condition that \(2x\) and \(x + z\) are integers, \(y\) is an arbitrary real number and \(u - 3x^2 \in \mathbb{Z}\).

The isotropy group of \(\text{Hei} \cdot (x, y, z) \in \text{Hei} \setminus \text{Hei}(\mathbb{R})\) contains \((\exp(2\pi i u), t^2)\) in its isotropy group under the \(S^1 \times \mathbb{Z}/4\)-action if and only if \((a - x, u + b + y - az, c - z) = (x, y, z)\) holds for some integers \(a, b, c\). Obviously the last statement is equivalent to the condition that \(2x, 2z\) and \(u - 2xz\) are integers and \(y\) is an arbitrary real number.

The isotropy group of \(\text{Hei} \cdot (x, y, z) \in \text{Hei} \setminus \text{Hei}(\mathbb{R})\) contains \((\exp(2\pi i u), 1)\) in its isotropy group under the \(S^1 \times \mathbb{Z}/4\)-action if and only if \((a + x, u + b + y + az, c + z) = (x, y, z)\) holds for some integers \(a, b, c\). The last statement is equivalent to the condition that \(x = 0, z = 0, u\) is an integer and \(y\) is an arbitrary real number.
This implies that the orbits under the $S^1 \times \mathbb{Z}/4$-action on $\text{Hei}(\mathbb{R})$ are free except the orbits through $\text{Hei}(1/2,0,1/2)$, whose isotropy group is the cyclic subgroup of order four generated by $(\exp(3\pi i/4), t)$, and the orbits through $\text{Hei}(0,0,0)$, whose isotropy group is the cyclic subgroup of order four generated by $(\exp(0), t)$, and the orbits through $\text{Hei}(-1/2,0,0)$ and $\text{Hei}(0,0,1/2)$, whose isotropy groups are the cyclic subgroup of order two generated by $(\exp(0), t^2)$. By the slice theorem any point $p \in \text{Hei}(\mathbb{R})$ has a neighborhood of the form $S^1 \times \mathbb{Z}/4 \times U_p$, where $U_p$ is its isotropy group and $U_p$ a 2-dimensional real $H_p$-representation, namely the tangent space of $\text{Hei}(\mathbb{R})$ at $p$. Since there are only finitely $S^1 \times \mathbb{Z}/4$-orbits which are non-free, the $H_p$-action on $U_p$ is free outside the origin for each $p \in \text{Hei}(\mathbb{R})$. In particular $H_p \backslash U_p$ is a manifold without boundary. If the isotropy group $H_p$ is mapped under the projection $p: S^1 \times \mathbb{Z}/4 \rightarrow S^1$ to the trivial group, then $\mathbb{Z}/4 \backslash (S^1 \times \mathbb{Z}/4 \times U_p)$ is $S^1$-homeomorphic to $S^1 \times H_p \backslash U_p$ and hence a free $S^1$-manifold without boundary. If the projection $p: S^1 \times \mathbb{Z}/4 \rightarrow S^1$ is injective on $H_p$, then $\mathbb{Z}/4 \backslash (S^1 \times \mathbb{Z}/4 \times U_p)$ is the $S^1$-manifold $S^1 \times H_p \backslash U_p$ with respect to the free $H$-action on $S^1$ induced by $p$ which has no boundary and precisely one non-free $S^1$-orbit. This shows that the quotient of $\text{Hei}(\mathbb{R})$ under the $\mathbb{Z}/4$-action is a closed $S^1$-manifold with precisely one non-free orbit.

The fixed point set of any finite subgroup of $G$ of the $G$-space $\text{Hei}(\mathbb{R}) = \mathbb{R}^3$ is a non-empty affine real subspace of $\text{Hei}(\mathbb{R}) = \mathbb{R}^2$ and hence contractible. This shows that $\text{Hei}(\mathbb{R})$ with its $G$-action is a model for $EG$. Hence $G \backslash EG$ is a closed $S^1$-manifold with precisely one non-free orbit, whose quotient space under the $S^1$-action is the orbit space of $T^2$ under the $\mathbb{Z}/4$-action. One easily checks for the rational homology

$$H_n((\mathbb{Z}/4)U^2; \mathbb{Q}) \cong H_n(T^2) \otimes \mathbb{Z}[\mathbb{Z}/4] \cong H_n(S^2; \mathbb{Q}).$$

This implies that the $S^1$-space $G \backslash EG$ is a Seifert bundle over $(\mathbb{Z}/4)U^2 \cong S^2$ with precisely one singular fiber. Since the orbifold fundamental group of this orbifold $S^2$ with precisely one cone point vanishes, the map $e: \pi_1(S^1) \rightarrow \pi_1(G \backslash EG)$ given by evaluating the $S^1$-action at some base point is surjective by [28, Lemma 3.2]. The Hurewicz map $h: \pi_1(G \backslash EG) \rightarrow H_1(G \backslash EG)$ is bijective since $\pi_1(G \backslash EG)$ is a quotient of $\pi_1(S^1)$ and hence is abelian. The composition

$$\pi_1(S^1) \xrightarrow{e} \pi_1(G \backslash EG) \xrightarrow{h} H_1(G \backslash EG)$$

agrees with the composition

$$\pi_1(S^1) \xrightarrow{h'} H_1(S^1) = H_1(\mathbb{Z}[\mathbb{R}] \xrightarrow{pr} H_1(\text{Hei}(\mathbb{R})) \xrightarrow{H_1(\text{Hei}(\mathbb{R}))} H_1(G \backslash EG),$$

where $h'$ is the Hurewicz map, $e'$ given by evaluating the $S^1$-operation and $pr$ is the obvious projection. The map $H_1(\mathbb{Z}[\mathbb{R}] \rightarrow H_1(\text{Hei}(\mathbb{R}))$ is trivial since the element $z \in \text{Hei}$ is a commutator, namely $[u,v]$. Hence $G \backslash EG$ is a simply connected closed Seifert fibered 3-manifold. We conclude from [28, Lemma 3.1] that $G \backslash EG$ is homeomorphic to $S^3$.

$\square$
Next we investigate what information Theorem 1.6 gives in combination with Lemma 2.4.

We have to analyze the maps
\[
c[i]_n : K_n(C^*_r(p^{-1}(M_i))) \to K_n(p^{-1}(M_i) \backslash E p^{-1}(M_i)),
\]
which are defined as the compositions
\[
K_n(C^*_r(p^{-1}(M_i))) \xrightarrow{\text{asmb}^{-1}} K_n(p^{-1}(M_i) \backslash E p^{-1}(M_i)) \xrightarrow{\text{ind}_{p^{-1}(M_i) \to \{1\}}} K_n(p^{-1}(M_i) \backslash E p^{-1}(M_i)).
\]

For \( i = 1 \) the group \( p^{-1}(M_i) \) is isomorphic to \( \mathbb{Z} \) and hence the maps \( c[i]_n \) are all isomorphisms. In the case \( i = 0, 2 \) the group \( p^{-1}(M_i) \) looks like \( H_i \times \mathbb{Z} \) for \( H_0 = \langle t \rangle \cong \mathbb{Z}/4 \) and \( H_2 = \langle ut^2 \rangle \cong \mathbb{Z}/2 \). The following diagram commutes
\[
\begin{array}{ccc}
K_n(C^*_r(H_i \times \mathbb{Z})) & \xrightarrow{\text{asmb}} & K_n^H(H_i) \times \mathbb{Z} \xrightarrow{\cong} K_n^H(\{\ast\}) \bigoplus K_{n-1}(\{\ast\}) \\
\downarrow & & \downarrow \\
K_n(C^*_r(\mathbb{Z})) & \xrightarrow{\text{asmb}} & K_n^E(\mathbb{Z}) \xrightarrow{\cong} K_n(\{\ast\}) \bigoplus K_{n-1}(\{\ast\})
\end{array}
\]

The map \( \text{ind}_{H_i \to \{1\}} : K_n^H(\{\ast\}) \to K_n(\{\ast\}) \) is the map \( \text{id} : 0 \to 0 \) for \( n \) odd. For \( n \) even it can be identified with the homomorphism \( \epsilon : R_C(H_i) \to \mathbb{Z} \) which sends the class of a complex \( H_i \)-representation \( V \) to the complex dimension of \( \mathbb{C} \otimes_{CH_i} V \). This map is split surjective. The kernel of \( \epsilon \) is denoted by \( \tilde{R}_C(H_i) \).

Define for \( i = 0, 2 \) maps
\[
c[i]''_n : \tilde{R}_C(H_i) \to K_n(C^*_r(G))
\]
as follows. For \( n \) even it is the composition
\[
\tilde{R}_C(H_i) \subseteq R_C(H_i) = K_n(C^*_r(H_i)) \xrightarrow{\text{asmb}} K_n(C^*_r(H_i)) \xrightarrow{\text{ind}_{H_i \to \{1\}}} K_n(C^*_r(G)),
\]
where \( l'_i : H_i \to G \) is the inclusion. For \( n \) odd it is the composition
\[
\tilde{R}_C(H_i) \subseteq R_C(H_i) = K_{n-1}(C^*_r(H_i)) \xrightarrow{\cong} K_n(C^*_r(H_i \times \mathbb{Z})) \xrightarrow{\text{asmb}} K_n(C^*_r(H_i \times \mathbb{Z})) \xrightarrow{\text{ind}_{H_i \times \mathbb{Z} \to \{1\}}} K_n(C^*_r(G)),
\]
where \( l_i : H_i \times \mathbb{Z} = p^{-1}(M_i) \to G \) is the inclusion and
\[
x_i \bigoplus K_n(y_i) : K_{n-1}(C^*_r(H_i)) \bigoplus K_n(C^*_r(H_i)) \xrightarrow{\cong} K_n(C^*_r(H_i \times \mathbb{Z}))
\]
is the canonical isomorphism for \( y_i : H_i \to H_i \times \mathbb{Z} \) the inclusion. The map
\[
\partial_n : K_n(G \backslash EG) \to \bigoplus_{i \in I} K_{n-1}(C^*_r(p^{-1}(M_i)))
\]
appearing in Theorem 1.6 vanishes after applying $\mathbb{Q} \otimes \mathbb{Z}$. Since the target is a finitely generated torsionfree abelian group, the map itself is trivial. Hence we obtain from Theorem 1.6 short exact sequences for $n \in \mathbb{Z}$

$$0 \to \tilde{R}_C(\mathbb{Z}/4) \bigoplus \tilde{R}_C(\mathbb{Z}/2) \xrightarrow{c[0][1] \bigoplus c[2][1]} K_n(C^*_r(G)) \twoheadrightarrow K_n(S^3) \to 0,$$

where we identify $H_0 = \langle t \rangle = \mathbb{Z}/4$ and $H_2 = \langle t^2 \rangle = \mathbb{Z}/2$ and $G \setminus EG = S^3$ using Lemma 2.4. If $j_n : K_n(\{\ast\}) = K_n(C^*_r(\{1\})) \to K_n(C^*_r(G))$ is induced by the inclusion of the trivial subgroup, we can rewrite the sequence above as the short exact sequence

$$0 \to K_n(\{\ast\}) \bigoplus \tilde{R}_C(\mathbb{Z}/4) \bigoplus \tilde{R}_C(\mathbb{Z}/2) \xrightarrow{j_n \bigoplus c[0][1] \bigoplus c[2][1]} K_n(C^*_r(G)) \twoheadrightarrow \tilde{K}_n(S^3) \to 0,$$

where $\tilde{K}_n(Y)$ is for a path connected space $Y$ the cokernel of the obvious map $K_n(\{\ast\}) \to K_n(Y)$. We have $\tilde{K}_0(S^3) = 0$ and $\tilde{K}_1(S^3) \cong \mathbb{Z}$. Thus we get

**Theorem 2.6.** We have the isomorphism

$$j_0 \bigoplus c[0][1] \bigoplus c[2][1] : K_0(\{\ast\}) \bigoplus \tilde{R}_C(\mathbb{Z}/4) \bigoplus \tilde{R}_C(\mathbb{Z}/2) \xrightarrow{\cong} K_0(C^*_r(\text{Hei} \times \mathbb{Z}/4))$$

and the short exact sequence

$$0 \to \tilde{R}_C(\mathbb{Z}/4) \bigoplus \tilde{R}_C(\mathbb{Z}/2) \xrightarrow{c[0][1] \bigoplus c[2][1]} K_1(C^*_r(G)) \twoheadrightarrow \tilde{K}_1(S^3) \to 0,$$

where the maps $c[i][j]$ have been defined in (2.5). In particular $K_n(C^*_r(G))$ is a free abelian group of rank five for all $n$.

**Remark 2.7.** These computations are consistent with the computation of $K_n(C^*_r(G)) [\frac{1}{2}]$ coming from the Chern character constructed in [18].

**Remark 2.8.** One can also use these methods to compute the topological $K$-theory of the real reduced group $C^*$-algebra $C^*_r(\text{Hei} \times \mathbb{Z}/4; \mathbb{R})$. One obtains the short exact sequence

$$0 \to KO_n(\{\ast\}) \bigoplus \tilde{K}_n(C^*_r(\mathbb{Z}/2; \mathbb{R})) \bigoplus \tilde{K}_{n-1}(C^*_r(\mathbb{Z}/2; \mathbb{R}))$$

$$\bigoplus \tilde{K}_n(C^*_r(\mathbb{Z}/4; \mathbb{R})) \bigoplus \tilde{K}_{n-1}(C^*_r(\mathbb{Z}/4; \mathbb{R}))$$

$$\to K_n(C^*_r(\text{Hei} \times \mathbb{Z}/4)) \to \tilde{K}O_n(S^3) \to 0,$$

which splits after inverting 2.
3 Algebraic $K$-theory

In this section we want to describe what the methods above yield for the algebraic $K$-theory provided that instead of the Baum-Connes Conjecture the relevant version of the Farrell-Jones Conjecture for algebraic $K$-theory (see [12]) is true. The $L$-theory will be treated in the next section. We want to prove

**Theorem 3.1.** Let $R$ be a regular ring, for instance $R = \mathbb{Z}$. Let $G$ be the group appearing in $(0,1)$ and assume that conditions $(M)$, $(NM)$, and $(T)$ are satisfied. Suppose that $G$ and all subgroups $p^{-1}(M_i)$ satisfy the Farrell-Jones Conjecture for algebraic $K$-theory with coefficients in $R$. Then we get for $n \in \mathbb{Z}$ the isomorphism

$$\bigoplus_{i \in I} \text{Wh}_n(Rl_i) : \text{Wh}_n(R[p^{-1}(M_i)]) \cong \text{Wh}_n(RG),$$

where $l_i : p^{-1}(M_i) \to G$ is the inclusion.

Notice that in the context of the Farrell-Jones Conjecture one has to consider the family of virtually cyclic subgroups $\mathcal{VC}$ and only under special assumptions it suffices to consider the family $\mathcal{FIN}$ of finite subgroups. Recall that a family $\mathcal{F}$ of subgroups is a set of subgroups closed under conjugation and taking subgroups and that a model for the classifying space $E_{\mathcal{F}}(G)$ for the family $\mathcal{F}$ is a $G$-CW-complex whose isotropy groups belong to $\mathcal{F}$ and whose $H$-fixed point set is contractible for each $H \in \mathcal{F}$. It is characterized up to $G$-homotopy by the property that any $G$-CW-complex, whose isotropy groups belong to $\mathcal{F}$, possesses up to $G$-homotopy precisely one $G$-map to $E_{\mathcal{F}}(G)$. In particular two models for $E_{\mathcal{F}}(G)$ are $G$-homotopy equivalent and for an inclusion of families $\mathcal{F} \subset \mathcal{G}$ there is up to $G$-homotopy precisely one $G$-map $E_{\mathcal{F}}(G) \to E_{\mathcal{G}}(G)$. The space $E_{\mathcal{G}}$ is the same as $E_{\mathcal{FLN}}(G)$.

Let $\mathcal{H}^G_n(X; K(R?))$ and $\mathcal{H}^G_n(X; L^{\langle -\infty \rangle}(R?))$ be the $G$-homology theories associated to the algebraic $K$ and $L$-theory spectra over the orbit category $K(R?)$ and $L^{\langle -\infty \rangle}(R?)$ (see [10]). They satisfy for each subgroup $H \subseteq G$

$$\mathcal{H}^G_n(G/H; K(R?)) \cong K_n(RH);$$

$$\mathcal{H}^G_n(G/H; L^{\langle -\infty \rangle}(R?)) \cong L_n^{\langle -\infty \rangle}(RH).$$

The **Farrell-Jones Conjecture** (see [12, 1.6 on page 257]) says that the projection $E_{\mathcal{VC}}(G) \to G/G$ induces isomorphisms

$$\mathcal{H}^G_n(E_{\mathcal{VC}}(G); K(R?)) \cong \mathcal{H}^G_n(G/G; K(R?)) = K_n(RG);$$

$$\mathcal{H}^G_n(E_{\mathcal{VC}}(G); L^{\langle -\infty \rangle}(R?)) \cong \mathcal{H}^G_n(G/G; L^{\langle -\infty \rangle}(R?)) = L_n^{\langle -\infty \rangle}(RG).$$

In the $L$-theory case one must use $L^{\langle -\infty \rangle}$. There are counterexamples to the Farrell-Jones Conjecture for the other decorations $p$, $h$ and $s$ (see [14]).

In the sequel we denote for a $G$-map $f : X \to Y$ by $\mathcal{H}^G_n(f; X \to Y; K(R?))$ the value of $\mathcal{H}^G_n$ on the pair given by the mapping cylinder of $f$ and $Y$ viewed
as a $G$-subspace. We will often use the long exact sequence associated to this pair

$$
\ldots \to \mathcal{H}^G_n(X; \mathbf{K}(R?)) \to \mathcal{H}^G_n(Y; \mathbf{K}(R?)) \to \mathcal{H}^G_n(f: X \to Y; \mathbf{K}(R?)) \\
\to \mathcal{H}^G_{n-1}(X; \mathbf{K}(R?)) \to \mathcal{H}^G_{n-1}(Y; \mathbf{K}(R?)) \to \ldots
$$

The following result is taken from [3].

**Theorem 3.2.** There are isomorphisms

$$
\mathcal{H}^G_n(\mathbf{EG}; \mathbf{K}(\mathbb{R}?)) \bigoplus \mathcal{H}^G_n(\mathbf{EG} \to E_{\mathcal{VQC}}(G); \mathbf{K}(R?)) \\
\cong \mathcal{H}^G_n(E_{\mathcal{VQC}}(G); \mathbf{K}(R?));
$$

$$
\mathcal{H}^G_n(\mathbf{EG}; \mathbf{L}^{(-\infty)}(\mathbb{R}?)) \bigoplus \mathcal{H}^G_n(\mathbf{EG} \to E_{\mathcal{VQC}}(G); \mathbf{L}^{(-\infty)}(R?)) \\
\cong \mathcal{H}^G_n(E_{\mathcal{VQC}}(G); \mathbf{L}^{(-\infty)}(R?)),
$$

where in the $K$-theory context $G$ and $R$ are arbitrary and in the $L$-theory context $G$ is arbitrary and we assume for any virtually cyclic subgroup $V \subseteq G$ that $K_{-i}(RV) = 0$ for sufficiently large $i$.

For a virtually cyclic group $V$ we have $K_{-i}(\mathbb{Z}V) = 0$ for $n \geq 2$ (see [13]).

The terms $\mathcal{H}^G_n(\mathbf{EG} \to E_{\mathcal{VQC}}(G); \mathbf{K}(R?))$ vanish for instance if $R$ is a regular ring containing $\mathbb{Q}$. The terms $\mathcal{H}^G_n(\mathbf{EG} \to E_{\mathcal{VQC}}(G); \mathbf{L}^{(-\infty)}(R?))$ vanish after inverting 2 (see Lemma 4.2). Recall that the Whitehead group $Wh_n(RG)$ is by definition $\mathcal{H}^G_n(\mathbf{EG} \to G/G; \mathbf{K}(R?))$. This implies that $Wh_n(RG) = \mathcal{H}^G_n(\mathbf{EG} \to E_{\mathcal{VQC}}(G); \mathbf{K}(R?))$ if the Farrell-Jones Isomorphism Conjecture for algebraic $K$-theory holds for $RG$. The group $Wh_1(\mathbb{Z}G)$ is the classical Whitehead group $Wh(G)$. If $R$ is a principal ideal domain, then $Wh_0(RG)$ is a field and $Wh_n(RG) = K_n(RG)$ for $n \leq -1$.

If we cross the $\mathbb{Q}$-pushout (1.1) with $E_{\mathcal{VQC}}(G)$ we obtain the $G$-pushout

$$
\prod_{i \in I} G \times_{p^{-1}(M_i)} E_{\mathcal{VQC}}(K \cap p^{-1}(M_i)) (p^{-1}(M_i)) \longrightarrow E_{\mathcal{VQC}}(K(G))
$$

$$
\prod_{i \in I} G \times_{p^{-1}(M_i)} E_{\mathcal{VQC}}(p^{-1}(M_i)) \longrightarrow E_{\mathcal{VQC}_f}(G)
$$

where $\mathcal{VQC}(K \cap p^{-1}(M_i))$ is the family of virtually cyclic subgroups of $p^{-1}(M_i)$, which are contained in $K \cap p^{-1}(M_i)$, and $\mathcal{VQC}(K)$ is the family of virtually cyclic subgroups of $G$, which are contained in $K$, and $\mathcal{VQC}_f$ is the family of virtually cyclic subgroups of $G$, whose image under $p: G \to Q$ is finite. Since $K$ is torsionfree, elements in $\mathcal{VQC}(K \cap p^{-1}(M_i))$ and $\mathcal{VQC}(K)$ are trivial or infinite cyclic groups. The following result is taken from [22, Theorem 2.3].
Theorem 3.4. Let \( \mathcal{F} \subset \mathcal{G} \) be families of subgroups of the group \( \Gamma \). Let \( \Lambda \) be a ring with \( \mathbb{Z} \subseteq \Lambda \subseteq \mathbb{Q} \) and \( N \) be an integer. Suppose for every \( H \in \mathcal{G} \) that the assembly map induces for \( n \leq N \) an isomorphism

\[
\Lambda \otimes \mathbb{Z} H_n^H(E_{H \cap \mathcal{F}}(H); \mathbf{K}(R?)) \to \Lambda \otimes \mathbb{Z} H_n^H(H/H; \mathbf{K}(R?)),
\]

where \( H \cap \mathcal{F} \) is the family of subgroups \( K \leq H \) with \( K \in \mathcal{F} \). Then the map

\[
\Lambda \otimes \mathbb{Z} H_n^H(E_\mathcal{F}(\Gamma); \mathbf{K}(R?)) \to \Lambda \otimes \mathbb{Z} H_n^\Gamma(E_\mathcal{G}(\Gamma); \mathbf{K}(R?))
\]

is an isomorphism for \( n \leq N \). The analogous result is true for \( \mathbf{L}^{1-\infty}(R?) \) instead of \( \mathbf{K}(R?) \).

In the sequel we will apply Theorem 3.4 using the fact that for a finite cyclic group or an infinite dihedral group \( H \) the map

\[
as_{\text{b}} : H_n^H(E(\mathbb{Z}) \mathbf{K}(R?)) \to H_n^H(H/\mathbb{Z}; \mathbf{K}(R?)) = K_n(RH)
\]

is bijective for \( n \in \mathbb{Z} \). This follows for the infinite cyclic group from the Bass-Heller-decomposition and for the infinite dihedral group from Waldhausen [32, Corollary 11.5 and the following Remark] (see also [4] and [21, Section 2.2]).

The Farrell-Jones Conjecture for algebraic \( K \)-theory for the trivial family \( \mathcal{T} \mathcal{R} \) consisting of the trivial subgroup only is true for infinite cyclic groups and regular rings \( R \) as coefficients. We conclude from Theorem 3.4 that for a regular ring \( R \) the maps

\[
H_n^{p^{-1}(M_i)}(E(p^{-1}(M_i)); \mathbf{K}(R?)) \cong H_n^{p^{-1}(M_i)}(E_{\mathcal{V}\mathcal{C}(K)}(p^{-1}(M_i)); \mathbf{K}(R?))
\]

and

\[
H_n^G(EG; \mathbf{K}(R?)) \cong H_n^G(E_{\mathcal{V}\mathcal{C}(K)}(G); \mathbf{K}(R?))
\]

are bijective for all \( n \in \mathbb{Z} \). Hence we obtain for a regular ring \( R \) from the \( G \)-pushout (3.3) an isomorphism

\[
\bigoplus_{i \in I} H_n^{p^{-1}(M_i)}(E(p^{-1}(M_i)) \to E_{\mathcal{V}\mathcal{C}(p^{-1}(M_i)); \mathbf{K}(R?)) \cong H_n^G(EG \to E_{\mathcal{V}\mathcal{C}(G); \mathbf{K}(R?)}. \tag{3.5}
\]

Let \( \mathcal{V}\mathcal{C}_1 \) be the family of virtually cyclic subgroups of \( G \) whose intersection with \( K \) is trivial. Since \( \mathcal{V}\mathcal{C} \) is the union \( \mathcal{V}\mathcal{C}_f \cup \mathcal{V}\mathcal{C}_1 \) and the intersection \( \mathcal{V}\mathcal{C}_f \cap \mathcal{V}\mathcal{C}_1 \) is \( \mathcal{F}\mathcal{L}\mathcal{V} \), we obtain a \( G \)-pushout

\[
\begin{array}{ccc}
E_G & \longrightarrow & E_{\mathcal{V}\mathcal{C}_1}(G) \\
\downarrow & & \downarrow \\
E_{\mathcal{V}\mathcal{C}_f}(G) & \longrightarrow & E_{\mathcal{V}\mathcal{C}}(G)
\end{array}
\tag{3.6}
\]
The following conditions are equivalent for a virtually cyclic group $V$: i.) $V$ admits an epimorphism to $\mathbb{Z}$ with finite kernel, ii.) $H_1(V;\mathbb{Z})$ is infinite, iii.) The center of $V$ is infinite. A virtually cyclic subgroup does not satisfy these three equivalent conditions if and only if it admits an epimorphism onto $D_\infty$ with finite kernel.

**Lemma 3.7.** Any virtually cyclic subgroup of $Q$ is finite, infinite cyclic or isomorphic to $D_\infty$.

**Proof.** Suppose that $V \subseteq Q$ is an infinite virtually cyclic subgroup. Choose a finite normal subgroup $F \subseteq V$ such that $V/F$ is $\mathbb{Z}$ or $D_\infty$. We have to show that $F$ is trivial. Suppose $F$ is not trivial. By assumption there is a unique maximal finite subgroup $M \subseteq Q$ with $F \subseteq M$. Consider $q \in N_GF$. Then $F \subseteq q^{-1}Mq \cap M$. This implies $q \in N_GM = M$. Hence $N_GF$ is contained in the finite group $M$ what contradicts $V \subseteq N_GF$. Hence $F$ must be trivial. \hfill \square

Now we can prove Theorem 3.1.

**Proof.** Lemma 3.7 implies that any infinite subgroup appearing in $\mathcal{K}_1$ is an infinite cyclic group or an infinite dihedral group. Hence Theorem 3.4 implies that $\mathcal{H}_n^G(E_G \to E_{\mathcal{K}_1}(G); K(R))$ vanishes for $n \in \mathbb{Z}$. We conclude from the $G$-pushout (3.6) that $\mathcal{H}_n^G(E_{\mathcal{K}_1}(G) \to E_{\mathcal{K}_1}(G); K(R))$ vanishes for $n \in \mathbb{Z}$. Now Theorem 3.1 follows from (3.5). \hfill \square

Now let us investigate what the results above imply for the middle and lower algebraic $K$-theory with integral coefficients of the group $G = \text{Hei} \times \mathbb{Z}/4$ introduced in Section 2 and $R = \mathbb{Z}$. The Farrell-Jones Conjecture for algebraic $K$-theory is true for $G$ and $R = \mathbb{Z}$ in the range $n \leq 1$ since $G$ is a discrete cocompact subgroup of the virtually connected Lie group $\text{Hei}(\mathbb{R}) \times \mathbb{Z}/4$ (see [12]). Each group $p^{-1}(M_i)$ is virtually cyclic and satisfies the Farrell-Jones Conjecture for algebraic $K$-theory for trivial reasons. From Theorem 3.1 we get for $n \leq 1$ an isomorphism

$$Wh_n(p^{-1}(M_0)) \bigoplus Wh_n(p^{-1}(M_1)) \bigoplus Wh_n(p^{-1}(M_2)) \cong Wh_n(G),$$

which comes from the various inclusions of subgroups and the subgroups $M_0$, $M_1$ and $M_2$ of $Q$ have been introduced in Lemma 2.2. The Bass-Heller-Swan decomposition yields for any group $H$ an isomorphism

$$Wh_n(H \times \mathbb{Z}) \cong Wh_{n-1}(H) \bigoplus Wh_n(H) \bigoplus NK_n(\mathbb{Z}H) \bigoplus NK_n(\mathbb{Z}H).$$

(3.8)

The groups $Wh_n(\mathbb{Z}^k)$ and $Wh_n(\mathbb{Z}/2 \times \mathbb{Z}^k)$ vanish for $n \leq 1$ and $k \geq 0$. The groups $Wh_n(\mathbb{Z}/4)$ are trivial for $n \leq 1$. References for these claims are given in the proof of [22, Theorem 3.2]. The groups $Wh_n(\mathbb{Z}/4 \times \mathbb{Z}^k)$ vanish for $n \leq -1$ and $k \geq 0$. This follows from [13]. Thus we get
Corollary 3.9. Let $G$ be the group $\text{Hei} \times \mathbb{Z}/4$ introduced in Section 2. Then

$$\text{Wh}_n(G) \cong \begin{cases} N\mathcal{K}_n(\mathbb{Z}/4) \oplus N\mathcal{K}_n(\mathbb{Z}/4) & \text{for } n = 0, 1; \\ 0 & \text{for } n \leq -1. \end{cases} \quad (3.10)$$

where the isomorphism for $n = 0, 1$ comes from the inclusions of the subgroup $p^{-1}(M_0) = \langle t, z \rangle = \mathbb{Z} \times \mathbb{Z}/4$ into $G$ and the Bass-Heller-Swan decomposition (3.8).

Some information about $N\mathcal{K}_n(\mathbb{Z}/4)$ is given in [5, Theorem 10.6 on page 695]. Their exponent divides $4^d$ for some natural number $d$.

4 \quad L\text{-theory}

In this section we want to describe what the methods above yield for the algebraic $L$-theory provided that instead of the Baum-Connes Conjecture the relevant version of the Farrell-Jones Conjecture for algebraic $L$-theory (see [12]) is true.

Theorem 4.1. Let $G$ be the group appearing in (0.1) and assume that conditions (M), (NM), and (T) are satisfied. Suppose that $G$ and all the groups $p^{-1}(M)$ for $M \subseteq Q$ maximal finite satisfy the Farrell-Jones Conjecture for $L$-theory with coefficients in $R$.

(i) Then there is a long exact sequence of abelian groups

$$\ldots \rightarrow \mathcal{H}_{n+1}(G\backslash EG; \mathbb{L}^{(-\infty)}(R)) \rightarrow \bigoplus_{i \in I} L_{i-n}^{(-\infty)}(R[p^{-1}(M_i)])$$

$$\rightarrow \mathcal{H}_n^{G}(EG; \mathbb{L}^{(-\infty)}(R)) \oplus \left( \bigoplus_{i \in I} \mathcal{H}_n(p^{-1}(M_i) \setminus EP^{-1}(M_i); \mathbb{L}^{(-\infty)}(R)) \right)$$

$$\rightarrow \mathcal{H}_n(G\backslash EG; \mathbb{L}^{(-\infty)}(R)) \rightarrow \bigoplus_{i \in I} L_{i-n}^{(-\infty)}(R[p^{-1}(M_i)]) \rightarrow \ldots .$$

Let $\Lambda$ be a ring with $\mathbb{Z} \subseteq \Lambda \subseteq \mathbb{Q}$ such that the order of each finite subgroup of $G$ is invertible in $\Lambda$. Then the long exact sequence above reduces after applying $\Lambda \otimes_{\mathbb{Z}} -$ to short split exact sequences of $\Lambda$-modules

$$0 \rightarrow \bigoplus_{i \in I} \Lambda \otimes_{\mathbb{Z}} L_{i-n}^{(-\infty)}(R[p^{-1}(M_i)]) \rightarrow \Lambda \otimes_{\mathbb{Z}} \mathcal{H}_n^{G}(EG; \mathbb{L}^{(-\infty)}(R))$$

$$\bigoplus_{i \in I} \left( \bigoplus \mathcal{H}_n(p^{-1}(M_i) \setminus EP^{-1}(M_i); \mathbb{L}^{(-\infty)}(R)) \right)$$

$$\rightarrow \Lambda \otimes_{\mathbb{Z}} \mathcal{H}_n(G\backslash EG; \mathbb{L}^{(-\infty)}(R)) \rightarrow 0;$$
(ii) Suppose for any virtually cyclic subgroup \( V \subseteq G \) that \( K_{-i}(RV) = 0 \) for sufficiently large \( i \). Then there is a canonical isomorphism

\[
\mathcal{H}_n^G(EG; \mathbb{L}^{(-\infty)}(\mathbb{R}^2)) \bigoplus \mathcal{H}_n^G(EG \rightarrow E_{\mathcal{QC}}(G); \mathbb{L}^{(-\infty)}(R^2)) \xrightarrow{\cong} L_n^{(-\infty)}(RG);
\]

(iii) We have

\[
\mathcal{H}_n^G(EG \rightarrow E_{\mathcal{QC}}(G); \mathbb{L}^{(-\infty)}(R^2)) \left[ \frac{1}{2} \right] = 0.
\]

Proof. (i) is proven completely analogous to Theorem 1.6.

(ii) follows from Theorem 3.2.

(iii) follows from the next Lemma 4.2. \( \square \)

Lemma 4.2. Let \( \Gamma \) be a group. Let \( \mathcal{VQC} \) be the family of virtually cyclic subgroups of \( \Gamma \) and \( \mathcal{VQC}_Z \) be the subfamily of \( \mathcal{VQC} \) consisting of subgroups of \( \Gamma \) which admit an epimorphism to \( \mathbb{Z} \) with finite kernel. Let \( \mathcal{F} \) and \( \mathcal{G} \) be families of subgroups of \( \Gamma \). If \( \mathcal{FIN} \subseteq \mathcal{F} \subseteq \mathcal{G} \subseteq \mathcal{VQC}_Z \) holds, then

\[
\mathcal{H}_n^\Gamma \left( E_{\mathcal{F}}(\Gamma) \rightarrow E_{\mathcal{G}}(\Gamma); \mathbb{L}^{(-\infty)}(R^2) \right) = 0.
\]

If \( \mathcal{FIN} \subseteq \mathcal{F} \subseteq \mathcal{G} \subseteq \mathcal{VQC} \) holds, then

\[
\mathcal{H}_n^\Gamma \left( E_{\mathcal{F}}(\Gamma) \rightarrow E_{\mathcal{G}}(\Gamma); \mathbb{L}^{(-\infty)}(R^2) \right) \left[ \frac{1}{2} \right] = 0.
\]

Proof. From Theorem 3.4 we conclude that it suffices to show for a virtually cyclic group \( V \), which admits an epimorphism to \( \mathbb{Z} \), that the map

\[
\mathcal{H}_n^V(EG; \mathbb{L}^{(-\infty)}(R^2)) \rightarrow L_n^{(-\infty)}(RV)
\]

is bijective and for a virtually cyclic group \( V \), which admits an epimorphism to \( D_{\infty} \), that the map above is bijective after inverting two.

We begin with the case, where \( V = F \times_\phi \mathbb{Z} \) for an automorphism \( \phi: F \rightarrow F \) of a finite group \( F \). There is a long exact sequence which can be derived from [25] and [26]

\[
\cdots \rightarrow L_n^{(-\infty)}(RF) \xrightarrow{id - L_n^{(-\infty)}(R\phi)} L_n^{(-\infty)}(RF) \rightarrow L_n^{(-\infty)}(RV) \rightarrow L_{n-1}^{(-\infty)}(RF) \xrightarrow{id - L_n^{(-\infty)}(R\phi)} L_{n-1}^{(-\infty)}(RF) \rightarrow \cdots
\]

Since \( \mathbb{R} \) with the action of \( V \) coming from the epimorphism to \( \mathbb{Z} \) and the action of \( \mathbb{Z} \) by translation is a model for \( E_V \), we also obtain a long exact Mayer-Vietoris sequence

\[
\cdots \rightarrow L_n^{(-\infty)}(RF) \xrightarrow{id - L_n^{(-\infty)}(R\phi)} L_n^{(-\infty)}(RF) \rightarrow \mathcal{H}_n^V(EG; \mathbb{L}^{(-\infty)}(R^2)) \rightarrow L_{n-1}^{(-\infty)}(RF) \xrightarrow{id - L_n^{(-\infty)}(R\phi)} L_{n-1}^{(-\infty)}(RF) \rightarrow \cdots
\]
These two sequences are compatible with the assembly map

\[ \text{asmb: } \mathcal{H}_n^V(EV; L^{(-\infty)}(R?)) \rightarrow \mathcal{H}_n^V(V/V; L^{(-\infty)}(R?)) = L_n^{(-\infty)}(RV), \]

which must be an isomorphism by the Five-Lemma.

Suppose that \( V \) admits an epimorphism onto \( D_\infty = \mathbb{Z}/2 \ast \mathbb{Z}/2 \). Then we can write \( V \) as an amalgamated product \( F_1 \ast_{F_0} F_2 \) for finite groups \( F_1 \) and \( F_2 \) and a common subgroup \( F_0 \). We can think of \( V \) as a graph of groups associated to a segment and obtain an action without inversions on a tree which yields a 1-dimensional model for \( EV \) with two equivariant 0-cells \( V/F_1 \) and \( V/F_2 \) and one equivariant one-cell \( V/F_0 \times D^1 \) (see [29, §5]). The associated long Mayer-Vietoris sequence looks like

\[ \ldots \rightarrow L_n^{(-\infty)}(RF_0) \rightarrow L_n^{(-\infty)}(RF_1) \bigoplus L_n^{(-\infty)}(RF_2) \rightarrow \mathcal{H}_n^V(EV; L^{(-\infty)}(R?)) \]

\[ \rightarrow L_{n-1}^{(-\infty)}(RF_0) \rightarrow L_{n-1}^{(-\infty)}(RF_1) \bigoplus L_{n-1}^{(-\infty)}(RF_2) \rightarrow \ldots. \]

There is a corresponding exact sequence, where \( \mathcal{H}_n^V(EV; L^{(-\infty)}(R?)) \) is replaced by \( L_n^{(-\infty)}(RV) \) and additional UNIL-terms occur which vanish after inverting two (see for \( Z \subseteq R \subseteq \mathbb{Q} \) [7, Corollary 6] or see [27, Remark 8.7] and [25]). Now a Five-Lemma argument proves the claim.

\[ \square \]

**Theorem 4.3.** Let \( G \) be the group appearing in (0.1) and assume that conditions (M), (NM), and (T) are satisfied. Suppose that \( Q \) contains no element of order 2. Suppose that \( G \) and all the groups \( p^{-1}(M) \) for \( M \subseteq Q \) maximal finite satisfy the Farrell-Jones Conjecture for L-theory with coefficients in \( R \). Then there is a long exact sequence of abelian groups

\[ \ldots \rightarrow \mathcal{H}_{n+1}(G\backslash EG; L^{(-\infty)}(R?)) \rightarrow \bigoplus_{i \in I} L_n^{(-\infty)}(R[p^{-1}(M_i)]) \]

\[ \rightarrow L_n^{(-\infty)}(RG) \bigoplus \left( \bigoplus_{i \in I} \mathcal{H}_n(p^{-1}(M_i)\backslash EP^{-1}(M_i); L^{(-\infty)}(R?)) \right) \]

\[ \rightarrow \mathcal{H}_n(G\backslash EG; L^{(-\infty)}(R?)) \rightarrow \ldots. \]

Let \( \Lambda \) be a ring with \( Z \subseteq \Lambda \subseteq \mathbb{Q} \) such that the order of each finite subgroup of \( G \) is invertible in \( \Lambda \). Then the long exact sequence above reduces after applying \( \Lambda \otimes \mathbb{Z} \to \) short exact sequences of \( \Lambda \)-modules

\[ 0 \rightarrow \bigoplus_{i \in I} \Lambda \otimes \mathbb{Z} L_n^{(-\infty)}(R[p^{-1}(M_i)]) \rightarrow \]

\[ \Lambda \otimes \mathbb{Z} L_n^{(-\infty)}(RG) \bigoplus \left( \bigoplus_{i \in I} \Lambda \otimes \mathbb{Z} \mathcal{H}_n(p^{-1}(M_i)\backslash EP^{-1}(M_i); L^{(-\infty)}(R)) \right) \]

\[ \rightarrow \Lambda \otimes \mathbb{Z} \mathcal{H}_n(G\backslash EG; L^{(-\infty)}(R)) \rightarrow 0. \]
Proof. Because of Theorem 4.1 and Lemma 4.2 it suffices to prove for an infinite virtually cyclic subgroup $V \subset G$ that $V$ admits an epimorphism to $\mathbb{Z}$. If $V \cap K$ is trivial, then $V$ is an infinite virtually cyclic subgroup of $Q$ and hence is isomorphic to $\mathbb{Z}$ by Lemma 3.7. Suppose that $V \cap K$ is non-trivial. Then $V$ can be written as an extension $1 \to K \cap V \to V \to p(V) \to 1$ for a finite subgroup $p(V) \subseteq Q$. The group $K \cap V$ is infinite cyclic and $p(V)$ must have odd order. Hence $V$ contains a central infinite cyclic subgroup. This implies that $V$ admits an epimorphism to $\mathbb{Z}$. \hfill $\Box$

From now on we assume that $Q$ is an extension $1 \to \mathbb{Z}^n \to Q \to F \to 1$ for a finite group $F$ such that the conjugation action of $F$ on $\mathbb{Z}^n$ is free outside the origin.

Let $V \subseteq Q$ be infinite virtually cyclic. Either $F$ is of odd order or $F$ has a unique element $f_2$ of order two [22, Lemma 6.2]. Because of Lemma 3.7 either $V$ is infinite cyclic or $V$ is isomorphic to $D_\infty$ and each element $v_2 \in V$ of order two is mapped under $Q \to F$ to the unique element $f_2 \in F$ of order two in $F$.

Suppose that $V \subseteq Q$ is isomorphic to $D_\infty$. Then $V$ contains at least one element $v_2 \in V$ of order two. Any other element of order two is of the shape $v_2u$ for $u \in V \cap \mathbb{Z}^n$. Hence $V$ is the subgroup $\langle v_2, V \cap \mathbb{Z}^n \rangle$ generated by $v_2$ and the infinite cyclic group $V \cap \mathbb{Z}^n$ regardless which element $v_2 \in V$ of order two we choose. For any infinite cyclic subgroup $C \subseteq \mathbb{Z}^n$ let $C_{\text{max}}$ be the kernel of the projection $\mathbb{Z}^n \to (\mathbb{Z}^n/C)/\text{tors}(\mathbb{Z}^n/C)$. This is the maximal infinite cyclic subgroup of $\mathbb{Z}^n$ which contains $C$. Define $V_{\text{max}} \subseteq Q$ to be
\[ V_{\text{max}} := \langle v_2, (V \cap \mathbb{Z}^n)_{\text{max}} \rangle. \]

The subgroup $V_{\text{max}}$ is isomorphic to $D_\infty$ and satisfies $V \subseteq V_{\text{max}}$. Moreover, it is a maximal virtually cyclic subgroup, i.e. $V_{\text{max}} \subseteq W$ for a virtually cyclic subgroup $W \subseteq Q$ implies $V_{\text{max}} = W$. Let $V \subseteq W$ be virtually cyclic subgroups of $Q$ such that $V \cong D_\infty$. Then $W \cong D_\infty$ and $V_{\text{max}} = W_{\text{max}}$. Hence each virtually cyclic subgroup $V$ with $V \cong D_\infty$ is contained in a unique maximal virtually cyclic subgroup of $Q$ isomorphic to $D_\infty$, namely $V_{\text{max}}$.

Next we show $N_G V = V$ if $V$ is a subgroup of $Q$ with $V \cong D_\infty$ and $V = V_{\text{max}}$. Let $v_2 \in V$ be an element of order two. Consider an element $q \in N_G V$. Then the conjugation action of $q$ on $\mathbb{Z}^n$ sends $V \cap \mathbb{Z}^n$ to itself. Hence the conjugation action of $q^2$ on $\mathbb{Z}^n$ induces the identity on $V \cap \mathbb{Z}^n$. This implies that $q$ is mapped under $Q \to F$ to the unit element or the unique element of order two $f_2$. Hence $q$ is of the shape $u$ or $v_2u$ for some $u \in \mathbb{Z}^n$. Since $(v_2u)v_2(v_2u)^{-1} = v_2uv_2u^{-1}v_2 = v_2u^2$ and $v_2u^{-1} = -v_2u^2$, we conclude $v_2u^2 \in V$. This implies that $u^2 \in V \cap \mathbb{Z}^n$.

Let $J$ be a complete system of representatives $V$ for the set of conjugacy classes $(V)$ of subgroups $V \subseteq Q$ with $V \cong D_\infty$ and $V = V_{\text{max}}$. In the sequel let $\mathcal{X}\mathcal{C}\mathcal{F}$ be the set of subgroups $H$ with are infinite cyclic or finite. By attaching equivariant cells we construct a model for $E_{\mathcal{X}\mathcal{C}\mathcal{F}}(Q)$ which contains $\coprod_{V \in J} Q \times V E_{\mathcal{X}\mathcal{C}\mathcal{F}}(V)$ as $Q$-CW-subcomplex. Define a $Q$-CW-complex $E_{\mathcal{X}\mathcal{C}\mathcal{F}}(Q)$ by the $Q$-
pushout

$$\coprod_{V \in J} Q \times V E_{\mathcal{VFC}}(V) \longrightarrow E_{\mathcal{VFC}}(Q)$$

$$\quad u_5 \downarrow \quad \quad \quad \quad \quad \quad \quad f_5$$

$$\coprod_{V \in J} Q/V \longrightarrow E_{\mathcal{VFC}}(Q)$$

where the map $u_5$ is the obvious projection and the upper horizontal arrow is the inclusion.

We have to show that $E_{\mathcal{VFC}}(Q)$ is a model for the classifying space for the family $\mathcal{VFC}$ of virtually cyclic subgroups of $Q$. Obviously all its isotropy groups belong to $\mathcal{VFC}$. Let $H \subseteq Q$ be a virtually cyclic group with $H \in \mathcal{VFC}$. Choose a map of sets $s : Q/V \rightarrow Q$ such that its composition with the projection $Q \rightarrow Q/V$ is the identity. For any $V$-space $X$, there is a homeomorphism

$$(Q \times_V X)^H \cong \coprod_{qV \in Q/V \atop s(qV)^{-1} H s(qV)} X^q, \quad (q, x) \mapsto s(qV)^{-1} q x,$$

whose inverse sends $x$ of the summand $X^q$ belonging to $qV \in Q/V$ with $s(qV)^{-1} H s(qV) \subseteq V$ to $(s(qV), x)$. Since $E_{\mathcal{VFC}}(Q)^H$ is contractible for each $qV \in Q/V$ with $s(qV)^{-1} H s(qV) \subseteq V$, the map $u_5^H$ is a homotopy equivalence. Hence $f_5^H$ is a homotopy equivalence. The space $E_{\mathcal{VFC}}(Q)^H$ is contractible. Therefore $E_{\mathcal{VFC}}(Q)^H$ is contractible. Let $H \subseteq Q$ be a virtually cyclic group with $H \not\in \mathcal{VFC}$. Then

$$\left( \coprod_{V \in J} Q/V \right)^H = \{ * \};$$

$$\quad (Q \times_V E_{\mathcal{VFC}}(V))^H = \emptyset;$$

$$\quad E_{\mathcal{VFC}}(Q)^H = \emptyset.$$

This implies that $E_{\mathcal{VFC}}(Q)^H = \{ * \}$ is contractible.

Recall that $\mathcal{VFC}_f$ is the family of virtually cyclic subgroups of $G$ whose image under $p : G \rightarrow Q$ is finite and $\mathcal{VFC}_1$ is the family of virtually cyclic subgroups of $G$ whose intersection with $K = \ker(p)$ is trivial. Let $\mathcal{VFC}_{iso,f}$ be the family of subgroups of $G$ whose image under $p : G \rightarrow Q$ is contained in $\mathcal{VFC}_f$. If we cross the $Q$-pushout (4.4) with $E_{\mathcal{VFC}}(G)$, we obtain the $G$-pushout

$$\coprod_{V \in J} G \times_{p^{-1}(V)} E_{\mathcal{VFC}}(p^{-1}(V)) \longrightarrow E_{\mathcal{VFC}_{iso,f}}(G)$$

$$\quad u_6 \downarrow \quad \quad \quad \quad \quad \quad \quad f_6$$

$$\coprod_{V \in J} G \times_{p^{-1}(V)} E_{\mathcal{VFC}}(p^{-1}(V)) \longrightarrow E_{\mathcal{VFC}}(G)$$

22
Because of Lemma 4.2 this $G$-pushout induces for $n \in \mathbb{Z}$ isomorphisms

$$
\bigoplus_{V \in J} \mathcal{H}_n^{-1}(V) \left( E_{p^{-1}(V)} \to E_{\text{VOC}}(p^{-1}(V)); L^{(-\infty)}(R) \right)
$$

$$
\cong \mathcal{H}_n^G \left( E_{\text{VOC}}(G) \to E_{\text{VOC}}(G); L^{(-\infty)}(R) \right).
$$

Now we conclude from Lemma 4.2

**Lemma 4.5.** Let $1 \to \mathbb{Z}^n \to Q \to F \to 1$ be an extension such that the conjugation action of $F$ on $\mathbb{Z}^n$ is free outside the origin. Let $1 \to K \overset{i}{\to} G \overset{p}{\to} Q \to 1$ be an extension. Suppose that for any virtually cyclic group $V \subseteq G$ with $p(V)$ finite there exists an epimorphism $V \to \mathbb{Z}$. (This condition is satisfied if $K$ is abelian and contained in the center of $G$.) Then there is an isomorphism

$$
\bigoplus_{V \in J} \mathcal{H}_n^{-1}(V) \left( E_{p^{-1}(V)} \to E_{\text{VOC}}(p^{-1}(V)); L^{(-\infty)}(R) \right)
$$

$$
\cong \mathcal{H}_n^G \left( E_G \to E_{\text{VOC}}(G); L^{(-\infty)}(R) \right).
$$

Next we apply Theorem 4.1 and Lemma 4.5 to the special example $G = \text{Hei} \times \mathbb{Z}/4$ introduced in Section 2. We begin with constructing an explicit choice for $J$ and determining the preimages $p^{-1}(V)$ for $V \in J$. Recall that $J$ is a complete system of representatives of the conjugacy classes $(V)$ of subgroups $V \subseteq Q$ with $V \cong D_\infty$ and $V = V_{\text{max}}$. Let $\text{IC}(\mathbb{Z}^2)$ be the set of infinite cyclic subgroups $L$ of $\mathbb{Z}^2$. Any subgroup $V \subseteq Q$ with $V \cong D_\infty$ can be written as $V = \langle v_2, V \cap \mathbb{Z}^2 \rangle$ for $v_2 \in V$ any element of order two. Hence we can write $V = \langle t^a, L \rangle$ for $L \in \text{IC}(\mathbb{Z}^2)$ and $a \in \mathbb{Z}^2$. We have $\langle t^a, L \rangle = \langle t^{a'}, L' \rangle$ if and only if $L = L'$ and $a - a' \in L = L'$. We have $V = V_{\text{max}}$ for $V = \langle t^a, L \rangle$ if and only if $L \subseteq \mathbb{Z}^2$ is maximal.

Let $\text{IC}^+(\mathbb{Z})$ be the subset for which $L \in \text{IC}(\mathbb{Z}^2)$ meets $\{(n_1, n_2) \in \mathbb{Z}^2 \mid n_1 \geq 0, n_2 > 0\}$. The $\mathbb{Z}/4$-action on $\mathbb{Z}^2$ induces a $\mathbb{Z}/2$-action on $L_1(\mathbb{Z}^2)$ by sending $L$ to $i \cdot L$. Notice that $\text{IC}^+(\mathbb{Z}^2)$ is a fundamental domain for this action, i.e. $\text{IC}(\mathbb{Z}^2)$ is the disjoint union of $\text{IC}^+(\mathbb{Z}^2)$ and its image under this involution.

We claim that a complete system of representatives of conjugacy classes $(V)$ of subgroups $V$ of $Q = \mathbb{Z}^2 \times \mathbb{Z}/4$ with $V \cong \mathbb{Z}^2$ is

$$
\begin{align*}
\langle t^2, (n_1, n_2) \rangle & \quad n_1 \text{ even;} \\
\langle t^2(0,1), (n_1, n_2) \rangle & \quad n_1 \text{ even;} \\
\langle t^2, (n_1, n_2) \rangle & \quad n_2 \text{ even;} \\
\langle t^2(1,0), (n_1, n_2) \rangle & \quad n_2 \text{ even;} \\
\langle t^2, (n_1, n_2) \rangle & \quad n_1 \text{ and } n_2 \text{ odd;} \\
\langle t^2(1,0), (n_1, n_2) \rangle & \quad n_1 \text{ and } n_2 \text{ odd,}
\end{align*}
$$

where $(n_1, n_2)$ runs through $\text{IC}^+ = \{(n_1, n_2) \in \mathbb{Z}^2 \mid n_1 > 0, n_2 \geq 0, (n_1, n_2) =$
This follows from the computations

\[
(m_1, m_2)^{-1}(t^2(n_1, n_2))(m_1, m_2) = t^2(n_1 + 2m_1, n_2 + 2m_2);
\]
\[
t(t^2(n_1, n_2))t^{-1} = t^2(-n_2, n_1);
\]
\[
t^2(t^2(n_1, n_2))(t^2)^{-1} = t^2(-n_1, -n_2).
\]

Now we list the preimages \( p^{-1}(V) \) of these subgroups above and determine their isomorphism type. We claim that they can be described by the following generators

\[
\begin{align*}
&\langle t^2, t^2(n_1, n_1, n_2/2, n_2), (0, 1, 0) \rangle & n_1 \text{ even;} \\
&\langle t^2(0, 0, 1), t^2(n_1, n_1, n_2/2, n_2), (0, 1, 0) \rangle & n_1 \text{ even;} \\
&\langle t^2, t^2(n_1, n_1, n_2/2, n_2), (0, 1, 0) \rangle & n_2 \text{ even;} \\
&\langle t^2(1, 0, 0), t^2(n_1, n_1, n_2/2, n_2), (0, 1, 0) \rangle & n_2 \text{ even;} \\
&\langle t^2, t^2(2n_1, 2n_1, n_2, n_2), (n_1, \frac{n_1 + n_2 + 1}{2}, n_2) \rangle & n_1 \text{ and } n_2 \text{ odd;} \\
&\langle t^2(1, 0, 0), t^2(2n_1 + 1, 2n_1, n_2 + n_2, 2n_2), (n_1, \frac{n_1 + n_2 + 1}{2}, n_2) \rangle & n_1 \text{ and } n_2 \text{ odd,}
\end{align*}
\]

where \((n_1, n_2)\) runs through \(IC^+ = \{(n_1, n_2) \in \mathbb{Z}^2 \mid n_1 > 0, n_2 \geq 0, (n_1, n_2) = 1\}\). This is obvious for the first four groups and follows for the last two groups from the computation

\[
\begin{align*}
(n_1, \frac{n_1 n_2 + 1}{2}, n_2)^2 &= (2n_1, 2n_1 n_2, 2n_2) \cdot (0, 1, 0); \\
(2n_1 + 1, 2n_1 n_2 + n_2, 2n_2) &= (1, 0, 0) \cdot (2n_1, 2n_1 n_2, 2n_2).
\end{align*}
\]

The first four groups are isomorphic to \(D_\infty \times \mathbb{Z}\) and the last two are isomorphic to the semi-direct product \(D_\infty \rtimes a \mathbb{Z}\) with respect to the automorphism \(a\) of \(D_\infty = \mathbb{Z}/2*\mathbb{Z}/2 = \langle s_1, s_2 \mid s_1^2 = s_2^2 = 1 \rangle\) which send \(s_1\) to \(s_2\) and \(s_2\) to \(s_1\). For the first four groups there are explicit isomorphisms from \(D_\infty \times \mathbb{Z} = \langle s_1, s_2, z \mid s_1^2 = s_2^2 = [s_1, z] = [s_2, z] = 1 \rangle\) which send \(s_1, s_2, z\) to the three generators appearing in the presentation above. Similarly for the last two groups there are explicit isomorphisms from \(D_\infty \rtimes a \mathbb{Z} = \langle s_1, s_2, z \mid s_1^2 = s_2^2 = 1, z^{-1}s_1z = s_2 \rangle\) which send \(s_1, s_2, z\) to the three generators appearing in the presentation above. We leave it to the reader to check that these generators appearing in the presentation above do satisfy the required relations.

Next we compute the groups \(\mathcal{H}_n^{D_\infty \times \mathbb{Z}}(E_{D_\infty \times \mathbb{Z}}(D_\infty \times \mathbb{Z}); L^\infty(\mathbb{Z})?)\) and \(\mathcal{H}_n^{D_\infty \rtimes a \mathbb{Z}}(E_{D_\infty \rtimes a \mathbb{Z}}(D_\infty \rtimes a \mathbb{Z}); L^\infty(\mathbb{Z})?)\). There is an obvious model for \(E_{D_\infty}\) namely \(\mathbb{R}\) with the trivial \(\mathbb{Z}\)-action and the action of \(D_\infty = \mathbb{Z} \rtimes a \mathbb{Z}/2\), which comes from the \(\mathbb{Z}\)-action by translation and the \(\mathbb{Z}/2\)-action given by \(-id_\mathbb{Z}\). From this we obtain an exact sequence

\[
0 \to L_{n-\infty}^1(R) \xrightarrow{f} L_{n-\infty}^2(R[\mathbb{Z}/2]) \bigoplus L_{n-\infty}^2(R[\mathbb{Z}/2]) \xrightarrow{g} \mathcal{H}_n^{D_\infty}(E_{D_\infty}; L(R (?) \to 0
\]

such that the composition of \(f\) with the obvious map

\[
\mathcal{H}_n^{D_\infty}(E_{D_\infty}; L(R (?) \to \mathcal{H}_n^{D_\infty}(E_{D_\infty}; L(R) = L_{n-\infty}^1(R[D_\infty]))
\]

24
is given by the two obvious inclusions \( \mathbb{Z}/2 \to D_\infty = \langle s_1, s_2 \mid s_1^2 = 1 \rangle \). Thus we obtain an isomorphism

\[
H_n^{D_\infty} \left( E_{D_\infty} \to E_{\text{VCQ}}(D_\infty); \mathbf{L}^{(-\infty)}(R?) \right) = \text{UNil}_n(\mathbb{Z}/2 * \mathbb{Z}/2; R),
\]

where \( \text{UNil}_n(\mathbb{Z}/2 * \mathbb{Z}/2; R) \) is the UNil-term appearing in the short split exact sequence

\[
0 \to L_n^{(-\infty)}(R) \to L_n^{(-\infty)}(R[\mathbb{Z}/2]) \oplus L_n^{(-\infty)}(R[\mathbb{Z}/2]) \oplus \text{UNil}_n(\mathbb{Z}/2 * \mathbb{Z}/2; R) \to L_n^{(-\infty)}(R[\mathbb{Z}/2 * \mathbb{Z}/2]) \to 0
\]

due to Cappell [7, Theorem 10]. For the computation of these terms \( \text{UNil}_n(\mathbb{Z}/2 * \mathbb{Z}/2; R) \) we refer to [2], [8] and [9]. They have exponent four and they are either trivial or are infinitely generated as abelian groups.

We can take as model for \( E(D_\infty \times \mathbb{Z}) \) the product \( E_{D_\infty} \times \mathbb{R} \), where \( \mathbb{Z} \) acts on \( \mathbb{R} \) by translation. We get from (4.8) and Lemma 4.2 using a Mayer-Vietoris argument an isomorphism

\[
H_n^{\mathbb{Z} \times D_\infty} \left( E(D_\infty \times \mathbb{Z}) \to E_{\text{VCQ}}(D_\infty \times \mathbb{Z}); \mathbf{L}^{(-\infty)}(R?) \right) \\
\simeq H_n^{D_\infty} \left( E_{D_\infty} \times \mathbb{R} \to E_{\text{VCQ}}(D_\infty) \times \mathbb{R}; \mathbf{L}^{(-\infty)}(R?) \right) \\
\simeq H_n^{D_\infty} \left( E_{D_\infty} \times S^1 \to E_{\text{VCQ}}(D_\infty) \times S^1; \mathbf{L}^{(-\infty)}(R?) \right) \\
\simeq \text{UNil}_n(\mathbb{Z}/2 * \mathbb{Z}/2; R) \bigoplus \text{UNil}_{n-1}(\mathbb{Z}/2 * \mathbb{Z}/2; R).
\]

Next we investigate \( D_\infty \rtimes_a \mathbb{Z} \). Let \( \mathcal{VCQ}(D_\infty) \) be the family of virtually cyclic subgroups of \( D_\infty \rtimes_a \mathbb{Z} \) which lie in \( D_\infty \) and let \( \mathcal{VCQ}_f \) be the family of virtually cyclic subgroups of \( \mathcal{VCQ}(D_\infty) \) whose intersection with \( D_\infty \) is finite. Then the family \( \mathcal{VCQ} \) of virtually cyclic subgroups of \( D_\infty \rtimes_a \mathbb{Z} \) is the union of \( \mathcal{VCQ}(D_\infty) \) and \( \mathcal{VCQ}_f \) and the family \( \mathcal{F}\mathcal{VCQ}_f \) of finite subgroups of \( D_\infty \rtimes_a \mathbb{Z} \) is the intersection of \( \mathcal{VCQ}(D_\infty) \) and \( \mathcal{VCQ}_f \). Hence we get a pushout of \( D_\infty \rtimes_a \mathbb{Z} \)-spaces

\[
\begin{array}{ccc}
E(D_\infty \rtimes_a \mathbb{Z}) & \longrightarrow & E_{\text{VCQ}}(D_\infty \rtimes_a \mathbb{Z}) \\
\downarrow & & \downarrow \\
E_{\text{VCQ}_f}(D_\infty \rtimes_a \mathbb{Z}) & \longrightarrow & E_{\text{VCQ}_f}(D_\infty \rtimes_a \mathbb{Z})
\end{array}
\]

Any finite subgroup of \( D_\infty \) is trivial or isomorphic to \( \mathbb{Z}/2 \). Any group \( \mathcal{V} \) which can be written as extension \( 1 \to \mathbb{Z}/2 \to \mathcal{V} \to \mathbb{Z} \to 1 \) is isomorphic to \( \mathbb{Z}/2 \rtimes \mathbb{Z} \). Hence any infinite group \( \mathcal{V} \) occurring in \( \mathcal{VCQ}_f \) is isomorphic to \( \mathbb{Z} \) or \( \mathbb{Z}/2 \rtimes \mathbb{Z}/2 \). We conclude from Lemma 4.2 and the \( D_\infty \rtimes_a \mathbb{Z} \)-pushout above

\[
H_n^{D_\infty \rtimes_a \mathbb{Z}} \left( E_{\text{VCQ}}(D_\infty \rtimes_a \mathbb{Z}) \to E_{\text{VCQ}}(D_\infty \rtimes_a \mathbb{Z}); \mathbf{L}^{(-\infty)}(R?) \right) \\
\simeq H_n^{D_\infty \rtimes_a \mathbb{Z}} \left( E(D_\infty \rtimes_a \mathbb{Z}) \to E_{\text{VCQ}_f}(D_\infty \rtimes_a \mathbb{Z}); \mathbf{L}^{(-\infty)}(R?) \right) \simeq 0.
\]
Hence we get an isomorphism

$$
\mathcal{H}^{D_n \times \mathbb{Z}} (E(D_{\infty} \times_a \mathbb{Z}) \to E_{\mathcal{VC}} (D_{\infty} \times_a \mathbb{Z}); L^{(-\infty)} (R))
\cong \mathcal{H}^{D_n \times \mathbb{Z}} (E(D_{\infty} \times_a \mathbb{Z}) \to E_{\mathcal{VC}} (D_{\infty} \times_a \mathbb{Z}); L^{(-\infty)} (R)).
$$

We can take as model for $E(D_{\infty} \times_a \mathbb{Z})$ the to both sides infinite mapping telescope of the $(a: D_{\infty} \to D_{\infty})$-equivariant map $E_\alpha: E D_{\infty} \to E D_{\infty}$ with the $D_{\infty} \times_a \mathbb{Z}$-action for which $\mathbb{Z}$ acts by shifting the telescope to the right. A model for $E_{\mathcal{VC}} (D_{\infty} \times_a \mathbb{Z})$ is the to both sides infinite mapping telescope of the $(a: D_{\infty} \to D_{\infty})$-equivariant map $\{e\} \to \{e\}$. Of course this is the same as $\mathbb{R}$ with the $D_{\infty} \times_a \mathbb{Z}$-action, for which $D_{\infty}$ acts trivially and $\mathbb{Z}$ by translation. The long Mayer-Vietoris sequence together with (4.8) yields a long exact sequence

$$
\ldots \to \mathrm{UNil}_{n}(\mathbb{Z}/2 * \mathbb{Z}/2; R) \xrightarrow{\id - \mathrm{UNil}_{n} (a)} \mathrm{UNil}_{n}(\mathbb{Z}/2 * \mathbb{Z}/2; R)
\xrightarrow{} \mathcal{H}^{D_n \times \mathbb{Z}} (E(D_{\infty} \times_a \mathbb{Z}) \to E_{\mathcal{VC}} (D_{\infty} \times_a \mathbb{Z}); L^{(-\infty)} (R))
\to \mathrm{UNil}_{n-1}(\mathbb{Z}/2 * \mathbb{Z}/2; R) \xrightarrow{\id - \mathrm{UNil}_{n-1} (a)} \mathrm{UNil}_{n-1}(\mathbb{Z}/2 * \mathbb{Z}/2; R) \to \ldots
$$

(4.10)

**Theorem 4.11.** Let $G$ be the group $\mathbb{H} \times \mathbb{Z}/4$ introduced in Section 2. Then

(i) There is a short exact sequence which splits after inverting 2

$$
0 \to L^{(-\infty)} (\mathbb{Z}) \bigoplus L^{(-\infty)} (\mathbb{Z}[2]) \bigoplus L^{(-\infty)} (\mathbb{Z}[2])
\bigoplus L^{(-\infty)} (\mathbb{Z}[4]) \bigoplus L^{(-\infty)} (\mathbb{Z}[4])
\xrightarrow{\iota} \mathcal{H}^{G} (E G; L^{(-\infty)} (\mathbb{Z})) \to L^{(-\infty)} (\mathbb{Z}) \to 0;
$$

(ii) There is for $n \in \mathbb{Z}$ an isomorphism

$$
\mathcal{H}^{G} (E G; L^{(-\infty)} (\mathbb{Z})) \bigoplus \mathcal{H}^{G} (E G \to E_{\mathcal{VC}} (G); L^{(-\infty)} (\mathbb{Z})) \cong L^{(-\infty)} (Z G);
$$

(iii) Let $I C^{+}$ be the set $\{(n_1, n_2) \in \mathbb{Z}^2 \mid n_1 > 0, n_2 \geq 0, (n_1, n_2) = 1\}$. Then there is an isomorphism

$$
\left( \bigoplus_{\substack{(n_1, n_2) \in I C^{+} \text{ even} \quad \text{or} \quad n_1 \text{ or } n_2 \text{ odd}}}^{4} \left( \mathrm{UNil}_{n}(\mathbb{Z}/2 * \mathbb{Z}/2; \mathbb{Z}) \bigoplus \mathrm{UNil}_{n-1}(\mathbb{Z}/2 * \mathbb{Z}/2; \mathbb{Z}) \right) \right)
\bigoplus
cal{H}^{D_n \times \mathbb{Z}} (E(D_{\infty} \times_a \mathbb{Z}) \to E_{\mathcal{VC}} (D_{\infty} \times_a \mathbb{Z}); L^{(-\infty)} (R))
\cong \mathcal{H}^{G} (E G \to E_{\mathcal{VC}} (G); L^{(-\infty)} (\mathbb{Z})),
$$

26
where the term \( \mathcal{H}_n^{D_{\infty} \times \mathbb{Z}}(\mathbb{E}(D_{\infty} \times_a \mathbb{Z})) \rightarrow E_{\mathcal{MC}}(D_{\infty} \times_a \mathbb{Z}); L^{(-\infty)}(\mathbb{Z}/2) \) is analyzed in (4.10);

(iv) The canonical map \( L^{(-\infty)}(\mathbb{Z}/2) \xrightarrow{\cong} L^e(\mathbb{Z}/2) \) is bijective for all decorations \( e = p, h, s \).

Proof. (i) follows from Theorem 4.1 (i) since the groups \( \tilde{L}^p_n(\mathbb{Z}/2) = \tilde{I}^{(-\infty)}_n(\mathbb{Z}/2) \) and \( \tilde{L}^p_n(\mathbb{Z}/4) = \tilde{I}^{(-\infty)}_n(\mathbb{Z}/4) \) are torsionfree [1, Theorem 1].

(ii) The Farrell-Jones Conjecture for algebraic \( L \)-theory with coefficients in \( R = \mathbb{Z} \) is true for \( G = \text{Hei} \times \mathbb{Z}/4 \) and \( p^{-1}(V) \) for \( V \subseteq Q \) virtually cyclic since \( G \) is a discrete cocompact subgroup of the virtually connected Lie group \( \text{Hei}(\mathbb{R}) \times_a \mathbb{Z}/4 \) (see [12]). Since for a virtually cyclic group \( V \) we have \( K_n(\mathbb{Z}V) = 0 \) for \( n \leq -2 \) [13], we can apply Theorem 4.1 (ii).

(iii) This follows from Lemma 4.5, the lists (4.6) and (4.7) and the isomorphism (4.9).

(iv) Because of the Rothenberg sequences it suffices to show that the Tate cohomology groups \( \tilde{H}^n(\mathbb{Z}/2, \text{Wh}_q(G)) \) vanish for \( q \leq 1 \) and \( n \in \mathbb{Z} \). If \( q \leq -1 \), then \( \text{Wh}_q(G) = 0 \), and, if \( q = 0,1 \), then \( \text{Wh}_q(G) = NK_q(\mathbb{Z}[\mathbb{Z}/2]) \oplus NK_q(\mathbb{Z}[\mathbb{Z}/4]) \) by Corollary 3.9. One easily checks that the involution on \( \text{Wh}_q(G) \) corresponds under this identification to the involution on \( NK_q(\mathbb{Z}[\mathbb{Z}/2]) \oplus NK_q(\mathbb{Z}[\mathbb{Z}/4]) \) which sends \( (x_1, x_2) \) to \( (x_2, \tau(x_1)) \) for \( \tau : NK_q(\mathbb{Z}[\mathbb{Z}/4]) \rightarrow NK_q(\mathbb{Z}[\mathbb{Z}/4]) \) the involution on the Nil-Term. Hence the \( \mathbb{Z}[\mathbb{Z}/2]-\text{module} \) \( \text{Wh}_q(G) \) is isomorphic to the \( \mathbb{Z}[\mathbb{Z}/2]-\text{module} \) \( \mathbb{Z}[\mathbb{Z}/2] \otimes_{\mathbb{Z}} NK_q(\mathbb{Z}[\mathbb{Z}/4]), \) which is obtained from the \( \mathbb{Z}\)-module \( NK_q(\mathbb{Z}[\mathbb{Z}/4]) \) by induction with the inclusion of the trivial group into \( Z/2 \). This implies \( \tilde{H}^n(\mathbb{Z}/2, \text{Wh}_q(G)) = 0 \) for \( q \leq 1 \) and \( n \in \mathbb{Z} \). \( \square \)

Remark 4.12. If one inverts 2, then the computation for \( L_n(\mathbb{Z}[\text{Hei} \times \mathbb{Z}]) \) simplifies drastically as explained in the introduction because of Lemma 4.2. In general this example shows how complicated it is deal to deal with the infinite virtually cyclic subgroups which admit an epimorphism to \( D_{\infty} \) and the resulting UNil-terms.

5 Group homology

Finally we explain what the methods above give for the group homology

Theorem 5.1. Let \( G \) be the group appearing in (0.1) and assume that conditions (M), (NM), and (T) are satisfied. Then we obtain from the pushout (1.3) a long
exact Mayer–Vietoris sequence

\[
\ldots \to H_{n+1}(G \backslash EG) \xrightarrow{\partial_{n+1}} \bigoplus_{i \in I} H_n(p^{-1}(M_i)) \xrightarrow{(\bigoplus_{i \in I} H_n(l_i)) \oplus (\bigoplus_{i \in I} H_n(p^{-1}(M_i) \backslash g_i))} \bigoplus_{i \in I} H_n(G(p^{-1}(M_i) \backslash E)) \xrightarrow{\partial_n} H_n(G) \bigoplus_{i \in I} H_n(p^{-1}(M_i)) \xrightarrow{(\bigoplus_{i \in I} H_n(l_i)) \oplus (\bigoplus_{i \in I} H_n(p^{-1}(M_i) \backslash g_i))} \ldots,
\]

where \( l_i : p^{-1}(M_i) \to G \) is the inclusion, \( s_i : Ep^{-1}(M_i) \to Ep^{-1}(M_i) \), \( s : EG \to EG \) are the obvious equivariant maps and \( d_i : p^{-1}(M_i) \backslash Ep^{-1}(M_i) \to G \backslash EG \) is the map induced by the \( l_i \)-equivariant map \( Ep^{-1}(M_i) \to EG \).

Remark 5.2. Often there are finite-dimensional models for \( EG \) as discussed in [16], [17]. For instance, if there is a \( k \)-dimensional model for \( BK \) and a \( m \)-dimensional model for \( EQ \) and \( d \) is a positive integer such that the order of any finite subgroup of \( Q \) divides \( d \), then there is a \((dk + n)\)-dimensional model for \( EG \) [17, Theorem 3.1]. If \( Q \) is an extension \( 0 \to \mathbb{Z}^n \to Q \to F \to 1 \) for a finite group \( F \) and there is a \( k \)-dimensional model for \( BK \), then there is a \((|F| \cdot k + n)\)-dimensional model for \( EG \).

Suppose that there is a \( N \)-dimensional model for \( EG \). Then there is also a \( N \)-dimensional model for \( Ep^{-1}(M_i) \) for each \( i \in I \) and under the assumptions of Theorem 5.6 we obtain for \( n \geq N + 1 \) an isomorphism

\[
\bigoplus_{i \in I} H_n(l_i) : \bigoplus_{i \in I} H_n(p^{-1}(M_i)) \xrightarrow{\cong} H_n(G).
\]

Next we compute the group homology \( H_*(\text{Hei} \times \mathbb{Z}/4) \). We start with the computation of \( H_n(\text{Hei}) \). The Atiyah-Hirzebruch spectral sequence associated to the central extension \( 1 \to \mathbb{Z}^2 \xrightarrow{\gamma} \text{Hei} \xrightarrow{\lambda} \mathbb{Z}^2 \to 0 \) yields the isomorphism

\[
H_2(\mathbb{Z}^2) \xrightarrow{\cong} H_3(\text{Hei})
\]

and the long exact sequence

\[
0 \to H_1(\mathbb{Z}^2) \to H_2(\text{Hei}) \xrightarrow{H_2(\gamma)} H_2(\mathbb{Z}^2) \to H_0(\mathbb{Z}^2) = H_1(S^1) = H_1(\mathbb{Z}) \xrightarrow{H_1(\lambda)} H_1(\text{Hei}) \xrightarrow{H_1(\gamma)} H_1(\mathbb{Z}^2) \to 0.
\]

Since \( z \in \text{Hei} \) is a commutator, namely \([u, v] \), the map \( H_1(\lambda') : H_1(\mathbb{Z}) \to H_1(\text{Hei}) \) is trivial. This implies

28
Lemma 5.3. There are natural isomorphisms

\[
\begin{align*}
H_1(p') : H_1(\text{Hei}) & \xrightarrow{\cong} H_1(\mathbb{Z}^2); \\
H_1(\mathbb{Z}^2) & \xrightarrow{\cong} H_2(\text{Hei}); \\
H_2(\mathbb{Z}^2) & \xrightarrow{\cong} H_3(\text{Hei}); \\
H_n(\text{Hei}) & = 0 \quad \text{for } n \geq 4.
\end{align*}
\]

Next we analyze the Atiyah-Hirzebruch spectral sequence associated to the split extension \( 1 \to \text{Hei} \xrightarrow{k} G := \text{Hei} \times \mathbb{Z}/4 \xrightarrow{\pi} \mathbb{Z}/4 \to 1 \). The isomorphisms above appearing in the computation of the homology of \( \text{Hei} \) are compatible with the \( \mathbb{Z}/4 \)-actions. Thus we get

\[
\begin{align*}
H_p(\mathbb{Z}/4; H_q(\text{Hei})) & = H_p(\mathbb{Z}/4; H_q(\mathbb{Z}^2)) = \mathbb{Z}/2 \quad \text{for } q = 1, 2, p \geq 0, p \text{ even}; \\
H_p(\mathbb{Z}/4; H_q(\text{Hei})) & = H_p(\mathbb{Z}/4; H_q(\mathbb{Z}^2)) = 0 \quad \text{for } q = 1, 2, p \geq 0, p \text{ odd}; \\
H_p(\mathbb{Z}/4; H_q(\text{Hei})) & = H_p(\mathbb{Z}/4) \quad \text{for } q = 0, 3; \\
H_p(\mathbb{Z}/4; H_q(\text{Hei})) & = 0 \quad \text{for } q \geq 4.
\end{align*}
\]

Hence the \( E^2 \)-term looks like

\[
\begin{array}{cccccc}
\mathbb{Z} & \mathbb{Z}/4 & 0 & \mathbb{Z}/4 & 0 & \mathbb{Z}/4 & 0 \\
\mathbb{Z}/2 & 0 & \mathbb{Z}/2 & 0 & \mathbb{Z}/2 & 0 & \mathbb{Z}/2 \\
\mathbb{Z}/4 & 0 & \mathbb{Z}/4 & 0 & \mathbb{Z}/4 & 0 & \mathbb{Z}/4 & 0
\end{array}
\]

Using the model for \( EG \) of Lemma 2.4 we see that the map \( B\text{Hei} \to G\backslash EG \) can be identified with the quotient map \( B\text{Hei} \to \mathbb{Z}/4\backslash B\text{Hei} \) of an orientation preserving smooth \( \mathbb{Z}/4 \)-action on the closed orientable 3-manifold \( B\text{Hei} \), where the quotient is again a closed orientable 3-manifold and the action has at least one free orbit. Since we can compute the degree of a map by counting preimages of a regular value, the degree must be \( \pm 4 \). Recall that \( G \to \mathbb{Z}/4 \) is split surjective. These remarks imply together with the spectral sequence above

**Lemma 5.4.** The composition \( H_3(B\text{Hei}) \xrightarrow{H_3(Bk)} H_3(BG) \xrightarrow{H_3(G\backslash \delta)} H_3(G\backslash EG) \) is an injective map of infinite cyclic subgroups whose cokernel has order four. The map \( H_3(\text{Hei}) \to H_3(G) \) is injective and the order of the cokernel of the induced map \( H_3(G)/\text{tors}(H_3(G)) \to H_3(G\backslash EG) \) divides four;

Moreover, there are the following possibilities

(i) The differential \( d_{2,1}^2 : E^2_{2,1} \cong \mathbb{Z}/2 \to E^2_{0,2} \cong \mathbb{Z}/2 \) is trivial. Then \( H_2(G) \) is \( \mathbb{Z}/2 \). Moreover, either the group \( H_3(G) \) is \( \mathbb{Z} \times \mathbb{Z}/4 \) and the induced map \( H_3(\text{Hei}) \to H_3(G)/\text{tors}(H_3(G)) \) is an injective homomorphism of infinite cyclic groups whose cokernel has order two, or the group \( H_3(G) \) is \( \mathbb{Z} \times \mathbb{Z}/2 \times \mathbb{Z}/4 \) and the induced map \( H_3(\text{Hei}) \to H_3(G)/\text{tors}(H_3(G)) \) is an isomorphism of infinite cyclic groups.

(ii) The differential \( d_{2,1}^2 : E^2_{0,2} \cong \mathbb{Z}/2 \to E^2_{2,1} \cong \mathbb{Z}/2 \) is non-trivial. Then \( H_2(G) \) is 0.

29
It is not obvious how to compute the homology groups $H_n(G)$ for $G = \text{Hei} \times \mathbb{Z}/4$ from the Atiyah-Hirzebruch spectral sequence. Let us try Theorem 5.1. It yields the long exact Mayer Vietoris sequence

$$
\ldots \to H_{n+1}(G \setminus EG) \xrightarrow{\partial_{n+1}} \bigoplus_{i=0}^2 H_n(p^{-1}(M_i)) \\
\bigoplus_{i=0}^2 H_n(p^{-1}(M_i) \setminus S_i) \to H_n(G) \bigoplus \left( \bigoplus_{i=0}^2 H_n(p^{-1}(M_i) \setminus E^{-1}(M_i)) \right) \\
\bigoplus_{i=0}^2 H_{n-1}(p^{-1}(M_i)) \xrightarrow{\partial_n} \bigoplus_{i=0}^2 H_{n-1}(p^{-1}(M_i) \setminus S_i) \to \ldots
$$

where the maximal finite subgroups $M_0$, $M_1$ and $M_2$ of $Q$ have been introduced in Lemma 2.2. The map $s_i: p^{-1}(M_i) \setminus E^{-1}(M_i) \to p^{-1}(M_i) \setminus E^{-1}(M_i)$ can be identified with

$$s_0: B\{t, z\} = B\{t\} \times B\{z\} \xrightarrow{pr} B\{z\};$$

$$s_1: B\{ut\} \xrightarrow{id} B\{ut\};$$

$$s_2: B\{ut^2, z\} = B\{ut^2\} \times B\{z\} \xrightarrow{pr} B\{z\}.$$

Hence we obtain the exact sequence

$$
\ldots \to H_{n+1}(G) \bigoplus H_{n+1}\{\langle z \rangle\} \bigoplus H_{n+1}\{\langle ut \rangle\} \bigoplus H_{n+1}\{\langle z \rangle\} \\
\bigoplus_{i=0}^2 H_{n+1}(G \setminus EG) \xrightarrow{\partial_{n+1}^i} H_n(\langle t \rangle \times \langle z \rangle) \bigoplus H_n(\langle ut \rangle) \bigoplus H_n(\langle ut^2 \rangle \times \langle z \rangle) \\
H_n(G) \bigoplus H_n(\langle z \rangle) \bigoplus H_n(\langle ut \rangle) \bigoplus H_n(\langle z \rangle) \xrightarrow{\partial_n^i} H_n(G \setminus EG) \xrightarrow{d_n} \ldots
$$

where

$$\text{incl}_0': \langle t, z \rangle = \langle t \rangle \times \langle z \rangle \to G;$$

$$\text{incl}_1': \langle ut \rangle \to G;$$

$$\text{incl}_2': \langle ut, z \rangle = \langle ut \rangle \times \langle z \rangle \to G.$$
are the inclusions. This yields the exact sequence

\[ \ldots \to H_{n+1}(G) \xrightarrow{H_{n+1}(G \setminus \emptyset)} H_{n+1}(G \setminus EG) \]

\[ \xrightarrow{\delta_n} \bar{H}_n((t)) \bigoplus \bar{H}_{n-1}((t)) \bigoplus \bar{H}_n([u^2]) \bigoplus \bar{H}_{n-1}([w^2]) \]

\[ \to H_0(G) \xrightarrow{H_0(G \setminus \emptyset)} H_0(G \setminus EG) \xrightarrow{\delta_0} \ldots \] \hspace{1cm} (5.5)

Recall that \(G \setminus EG\) is \(S^3\). We conclude from Lemma 5.4 that the order of the cokernel of the map \(H_3(G \setminus \emptyset) : H_3(BG) \to H_3(G \setminus EG)\) divides four. Since the order of \(\bar{H}_2((t)) \bigoplus \bar{H}_1((t)) \bigoplus \bar{H}_2(e_1^2) \bigoplus \bar{H}_2(e_2^2)\) is eight, the long exact sequence above implies that the group \(H_2(G)\) is different from zero and that the group \(H_3(G)\) is isomorphic to \(Z \times Z/2 \times Z/4\). Now Lemma 5.4 and the long exact sequence (5.5) above imply

**Theorem 5.6.** For \(G = \text{Hei} \rtimes \mathbb{Z}/4\) we have isomorphisms

\[ H_n(G) = \mathbb{Z}/2 \times \mathbb{Z}/4 \text{ for } n \geq 1, n \neq 2, 3; \]

\[ H_2(G) = \mathbb{Z}/2; \]

\[ H_3(G) = \mathbb{Z} \times \mathbb{Z}/2 \times \mathbb{Z}/4. \]

The map \(H_3(\text{Hei}) \to H_3(G) / \text{tors}(H_3(G))\) is an isomorphism.

One can compute the group cohomology analogously or derive it from the homology by the universal coefficient theorem.

### 6 Survey over other extensions

There are other prominent extensions of \(*\text{Hei}\) which can be treated analogously to the case \(*\text{Hei} \rtimes \mathbb{Z}/4\). We give a brief summary of the topological \(K\)-theory and the algebraic \(K\)-theory below. In all cases \(G \setminus EG\) is \(S^3\).

#### 6.1 Order six symmetry

Consider the following automorphism \(\omega : \text{Hei} \to \text{Hei}\) of order 6 which sends \(u\) to \(v\), \(v\) to \(u^{-1}v\), and \(z\) to \(z\).

**Theorem 6.1.** For the group

\[ G = \text{Hei} \rtimes \mathbb{Z}/6 = \langle u, v, z, t | [u, v] = z, t^6 = 1, [u, z] = [v, z] = [t, z] = 1, \]

\[ tut^{-1} = v, tvt^{-1} = u^{-1}v \]

there is a short exact sequence

\[ 0 \to \bar{R}_C((t)) \to K_1(C^*_\text{r}(G)) \to \bar{K}_1(S^3) \to 0 \]

and an isomorphism

\[ R_C((t)) \xrightarrow{\simeq} K_0(C^*_\text{r}(G)). \]
There are isomorphisms

\[ \text{Wh}_n(G) \cong \begin{cases} \text{NK}_1(\mathbb{Z}[\mathbb{Z}/6]) \oplus \text{NK}_1(\mathbb{Z}[\mathbb{Z}/6]) & \text{for } n = 1; \\ \text{Wh}_{-1}(\mathbb{Z}/6) \cong \mathbb{Z} & \text{for } n = -1, 0; \\ 0 & \text{for } n \leq -2. \end{cases} \]

6.2 Order three symmetry

Next we deal with the \( \mathbb{Z}/3 \)-action on \( \text{Hei} \) given by \( \omega^2 \), where \( \omega \) is the automorphism of order six investigated in Subsection 6.1.

**Theorem 6.2.** For the group

\[ G = \text{Hei} \rtimes \mathbb{Z}/3 = \langle u, v, z, t \mid [u, v] = z, t^3 = 1, [u, z] = [v, z] = [t, z] = 1, \]

\[ tut^{-1} = u^{-1}v, tvt^{-1} = u^{-1}z^{-1} \]

there is a short exact sequence

\[ 0 \to \tilde{R}_C((t)) \to K_1(C^*_\epsilon(G)) \to \tilde{K}_1(S^3) \to 0 \]

and an isomorphism

\[ \tilde{R}_C((t)) \xrightarrow{\cong} K_0(C^*_\epsilon(G)). \]

We have \( \text{Wh}_n(G) = 0 \) for \( n \leq 2 \).

The \( L \)-groups \( L_n(\mathbb{Z}G) \) are independent of the choice of decoration \( \epsilon = -\infty, p, h, s \) and the reduced ones fit into a short split exact sequence

\[ 0 \to \tilde{L}_n^{(-\infty)}(\mathbb{Z}(t)) \bigoplus \tilde{L}_n^{(-\infty)}(\mathbb{Z}(t)) \to \tilde{L}_n^{(-\infty)}(\mathbb{Z}G) \to \tilde{L}_n^{(-\infty)}(\mathbb{Z}) \to 0. \]

6.3 Order two symmetry

Next we deal with the \( \mathbb{Z}/2 \)-action on \( \text{Hei} \) given by \( u \mapsto u^{-1}, v \mapsto v^{-1} \) and \( z \mapsto z \).

This is the square of the automorphism of order four used in the \( \mathbb{Z}/4 \)-case.

**Theorem 6.3.** For the group

\[ G = \text{Hei} \rtimes \mathbb{Z}/2 = \langle u, v, z, t \mid [u, v] = z, t^2 = 1, [u, z] = [v, z] = [t, z] = 1, \]

\[ tut^{-1} = u^{-1}, tvt^{-1} = v^{-1} \]

there is a short exact sequence

\[ 0 \to \bigoplus_{i=0}^{\infty} \tilde{R}_C(M_i) \to K_1(C^*_\epsilon(G)) \to \tilde{K}_1(S^3) \to 0 \]

and an isomorphism

\[ 0 \to K_0(\{s\}) \bigoplus \bigoplus_{i=0}^{\infty} \tilde{R}_C(M_i) \xrightarrow{\cong} K_0(C^*_\epsilon(G)), \]

32
where

\[ M_0 = \langle t \rangle; \]
\[ M_1 = \langle ut \rangle; \]
\[ M_2 = \langle vt \rangle. \]

We have \( \text{Wh}_n(G) = 0 \) for \( n \leq 2 \).
