

Latin squares with forbidden entries

Jonathan Cutler
Department of Mathematics
University of Nebraska - Lincoln

A square array is avoidable if there is a Latin square which differs from the array in every cell. We will present a generalization of a result of Chetwynd and Rhodes involving avoiding arrays with two entries in each cell. We in fact generalize their method of proof to give a result about avoiding arrays with arbitrarily many entries in each cell.

This is a joint work with Lars-Daniel Ohman.
