

CONGRUENCE PROPERTIES OF BINARY PARTITION FUNCTIONS

KATHERINE ANDERS, MELISSA DENNISON, BRUCE REZNICK, AND JENNIFER WEBER

ABSTRACT. Let \mathcal{A} be a finite subset of \mathbb{N} containing 0, and let $f(n)$ denote the number of ways to write n in the form $\sum \epsilon_j 2^j$, where $\epsilon_j \in \mathcal{A}$. We show that there exists a computable $T = T(\mathcal{A})$ so that the sequence $(f(n) \bmod 2)$ is periodic with period T . Variations and generalizations of this problem are also discussed.

1. INTRODUCTION

Let $\mathcal{A} = \{0 = a_0 < a_1 < \dots\}$ denote a finite or infinite subset of \mathbb{N} containing 0, and fix an integer $b \geq 2$. Let $f_{\mathcal{A},b}(n)$ denote the number of ways to write n in the form

$$(1.1) \quad n = \sum_{k=0}^{\infty} \epsilon_k b^k, \quad \epsilon_k \in \mathcal{A}.$$

The uniqueness of the standard base- b representation of $n \geq 0$ reflects the fact that $f_{\mathcal{A},b}(n) = 1$ for $\mathcal{A} = \{0, \dots, b-1\}$. For non-standard bases, the behavior of $f_{\mathcal{A},b}(n)$ has been studied primarily when $\mathcal{A} = \mathbb{N}$ or $b = 2$, in terms of congruences at special values, and also asymptotically. In this paper, we are concerned with the behavior of $f_{\mathcal{A},b}(n) \pmod{d}$, especially when $b = d = 2$, and when \mathcal{A} is finite.

We associate to \mathcal{A} its characteristic function $\chi_{\mathcal{A}}(n)$, and the generating function

$$(1.2) \quad \phi_{\mathcal{A}}(x) := \sum_{n=0}^{\infty} \chi_{\mathcal{A}}(n) x^n = \sum_{a \in \mathcal{A}} x^a = 1 + x^{a_1} + \dots.$$

Let

$$(1.3) \quad F_{\mathcal{A},b}(x) := \sum_{n=0}^{\infty} f_{\mathcal{A},b}(n) x^n$$

denote the generating function of $f_{\mathcal{A},b}(n)$. Viewing (1.1) as a partition problem, we find an immediate infinite product representation for $F_{\mathcal{A},b}(x)$:

$$(1.4) \quad F_{\mathcal{A},b}(x) = \prod_{k=0}^{\infty} \left(1 + x^{a_1 b^k} + \cdots\right) = \prod_{k=0}^{\infty} \phi_{\mathcal{A}}(x^{b^k}).$$

Observe that (1.1) implies that $n \equiv \epsilon_0 \pmod{b}$. Thus, every such representation may be rewritten as

$$(1.5) \quad n = \sum_{j=0}^{\infty} \epsilon_j b^j = \epsilon_0 + b \left(\sum_{j=0}^{\infty} \epsilon_{j+1} b^j \right).$$

Since $f_{\mathcal{A},b}(n) = 0$ for $n < 0$, we see that (1.5) gives the recurrence

$$(1.6) \quad f_{\mathcal{A},b}(n) = \sum_{\substack{a \in \mathcal{A}, \\ n \equiv a \pmod{b}}} f_{\mathcal{A},b}\left(\frac{n-a}{b}\right), \quad \text{for } n \geq 1.$$

Alternatively, decompose \mathcal{A} into residue classes mod b and write

$$(1.7) \quad \mathcal{A} = \bigcup_{i=0}^{b-1} \mathcal{A}_i, \quad \text{where } \mathcal{A}_i := \mathcal{A} \cap (b\mathbb{Z} + i).$$

If we write $\mathcal{A}_i = \{bv_{k,i} + i\}$, then for $m \geq 0$ and $0 \leq i \leq b-1$:

$$(1.8) \quad f_{\mathcal{A},b}(bm + i) = \sum_k f_{\mathcal{A},b}(m - v_{k,i}).$$

The initial condition $f_{\mathcal{A},b}(0) = 1$, combined with (1.6) or (1.8), is sufficient to determine $f_{\mathcal{A},b}(n)$ for all $n > 0$.

We say that a sequence (u_n) is *eventually periodic* if there exist integers $N \geq 0$, $T \geq 1$ so that, for $n \geq N$, $u_{n+T} = u_n$. The *period* of an eventually periodic sequence is the smallest such T . By extension, we say that the set \mathcal{A} is *eventually periodic* if the sequence of its characteristic function, $(\chi_{\mathcal{A}}(n))$, is eventually periodic. Equivalently, \mathcal{A} is eventually periodic if there exists T , and integers r_1, \dots, r_k , $k \geq 0$, $0 \leq r_i \leq T-1$, so that the symmetric set difference of \mathcal{A} and $\cup(T\mathbb{N} + r_i)$ is finite. In particular, if \mathcal{A} is finite or the complement of a finite set, then \mathcal{A} is eventually periodic.

The principal result of this paper is the relationship of $F_{\mathcal{A},2}(x)$ and $\phi_{\mathcal{A}}(x) \pmod{2}$.

Theorem 1.1. *As elements of $\mathbb{F}_2[[x]]$,*

$$(1.9) \quad F_{\mathcal{A},2}(x)\phi_{\mathcal{A}}(x) = 1.$$

Theorem 1.1 has an immediate corollary.

Corollary 1.2.

- (1) *If \mathcal{A} is finite, then there is a computable integer $T = T(\mathcal{A}) > 0$ so that for all $n \geq 0$, $f_{\mathcal{A},2}(n) \equiv f_{\mathcal{A},2}(n+T) \pmod{2}$.*

- (2) *If \mathcal{A} is infinite, the sequence $(f_{\mathcal{A},2}(n) \pmod{2})$ is eventually periodic if and only if $\phi_{\mathcal{A}}(x)$ is the power series of a rational function in $\mathbb{F}_2(x)$ if and only if the set \mathcal{A} is eventually periodic.*

It will follow from Corollary 1.2(1) that if \mathcal{A} is a finite set, and $T = T(\mathcal{A})$, then there is a *complementary* finite set $\mathcal{A}' = \{0 = b_0 < b_1 < \dots\}$ so that

$$(1.10) \quad \begin{aligned} f_{\mathcal{A},2}(n) \text{ is odd} &\iff n \equiv b_k \pmod{T} \text{ for some } b_k; \\ f_{\mathcal{A}',2}(n) \text{ is odd} &\iff n \equiv a_k \pmod{T} \text{ for some } a_k. \end{aligned}$$

Complementary sets needn't look very much alike. If $\mathcal{A} = \{0, 1, 4, 9\}$, then $T = 84$ and $|\mathcal{A}'| = 41$, with elements ranging from 0 to 75 (see Example 4.3).

One instance of Theorem 1.1 in the literature comes from the *Stern sequence* $(s(n))$ (see [11, 7, 9]), which is defined by

$$(1.11) \quad s(0) = 0, \quad s(1) = 1; \quad s(2n) = s(n), \quad s(2n+1) = s(n) + s(n+1) \quad \text{for } n \geq 1.$$

It was proved in [8] that $s(n) = f_{\{0,1,2\},2}(n-1)$, under which the recurrence (1.11) is a translation of (1.8). It is easy to prove, and has basically been known since [11, p.197], that $s(n)$ is even if and only if n is a multiple of three. A simple application of Theorem 1.1 shows that in $\mathbb{F}_2(x)$,

$$(1.12) \quad F_{\{0,1,2\},2}(x) = \frac{1}{1+x+x^2} = \frac{1+x}{1+x^3} = 1 + x + x^3 + x^4 + x^6 + x^7 + \dots$$

This result was generalized in [8, Th.2.14], using the infinite product (1.4). Here, let $\mathcal{A}_d = \{0, \dots, d-1\}$. Then $\phi_{\mathcal{A}_d}(x) = \frac{1-x^d}{1-x}$, so in $\mathbb{F}_2(x)$,

$$(1.13) \quad F_{\mathcal{A}_d,2}(x) = \frac{1+x}{1+x^d} = 1 + x + x^d + x^{d+1} + x^{2d} + x^{2d+1} + \dots$$

Thus, $f_{\mathcal{A}_d,2}(n)$ is odd if and only if $n \equiv 0, 1 \pmod{d}$.

We also show that there is no obvious ‘‘universal’’ generalization of Theorem 1.1 to $f_{\mathcal{A},b}(n) \pmod{d}$ when $(b, d) \neq (2, 2)$.

Theorem 1.3.

- (1) *If $(f_{\{0,1,2\},2}(n) \pmod{d})$ is eventually periodic with period T , then $(d, T) = (2, 3)$.*
 (2) *If $d \geq 2$ and $b \geq 3$, then $(f_{\{0,1\},b}(n) \pmod{d})$ is never eventually periodic.*

Thus, the Stern sequence has no periodicities mod $d \geq 3$ and, there exists \mathcal{A} whose representations in any base $b \geq 3$ have no periodicity modulo any $d \geq 2$.

Let $\nu_2(m)$ denote the largest power of 2 dividing m . In 1969, Churchhouse [4] conjectured, based on numerical evidence, that $f_{\mathbb{N},2}(n)$ is even for $n \geq 2$, that $4 \mid f_{\mathbb{N},2}(n)$ if and only if either $\nu_2(n-1)$ or $\nu_2(n)$ is a positive even integer, and that 8 never divides $f_{\mathbb{N},2}(n)$. He also conjectured that, for all even m ,

$$(1.14) \quad \nu_2(f_{\mathbb{N},2}(4m)) - \nu_2(f_{\mathbb{N},2}(m)) = \lfloor \frac{3}{2}(3\nu_2(m) + 4) \rfloor.$$

This conjecture was proved in the next few years by Rødseth, and by Gupta and generalized by Hirschhorn and Loxton, Rødseth, Gupta, Andrews, Gupta and Pleasants, and most recently by Rødseth and Sellers [10]. We refer the reader to [8, 10] for detailed references. The statements in Theorem 1.3 about the non-existence of recurrences do not apply to formulas such as (1.14). On the other hand, $\phi_{\mathbb{N},2}(x) = (1+x)^{-1}$, so Theorem 1.1 implies that $f_{\mathbb{N},2}(n)$ is even for $n \geq 2$.

The paper is organized as follows. In section two, we review some basic facts about polynomials and rational functions over \mathbb{F}_2 . In section three, we give two proofs of Theorem 1.1 and then prove Corollary 1.2. In section four, we present several examples and applications of Theorem 1.1, as well as a proof of Theorem 1.3.

Portions of the research in this paper were contained in the Ph.D. dissertation [5] of the second author, written under the supervision of the third author, and in the UIUC Summer 2010 Research Experiences for Graduate Students (REGS) project [1] of the first and fourth authors, written under the supervision of the third author.

The authors thank Bob McEliece for helpful correspondence.

2. BACKGROUND

There is an important relationship between rational functions in $\mathbb{F}_2[[x]]$ and eventually periodic sequences. We first recall some familiar facts about finite fields, identifying $\mathbb{Z}/p\mathbb{Z}$ with \mathbb{F}_p for prime p . The binomial theorem implies that for $a, b \in \mathbb{F}_p$, $(a+b)^p = a^p + b^p$, hence $(\sum a_i)^p = \sum a_i^p$. It follows from this fact and Fermat's Little Theorem that for any polynomial $f \in \mathbb{F}_p[x]$,

$$(2.1) \quad f(x) = \sum_{j=0}^m a_j x^j \implies f(x)^p = f(x^p).$$

If $f \in \mathbb{F}_2[x]$ is an irreducible polynomial of degree d (so $f(0) \neq 0$), then it is well-known that $f(x) \mid 1 + x^{2^d-1}$. Repeated application of (2.1) for $p = 2$ shows that $(1 + x^M)^{2^k} = 1 + x^{2^k \cdot M}$, hence if f is irreducible and $j \leq 2^k$, then $f(x)^j \mid 1 + x^{2^k \cdot (2^d-1)}$. This leads immediately to the following lemma (see [2, Thm.6.21]):

Lemma 2.1. *Suppose $h \in \mathbb{F}_2[x]$, $h(0) \neq 0$ and h can be factored over $\mathbb{F}_2[x]$ as*

$$(2.2) \quad h = \prod_{i=1}^s f_i^{e_i},$$

where the f_i are distinct irreducible polynomials with $\deg(f_i) = d_i$, and suppose $2^k \geq e_i$ for all i and some $k \in \mathbb{N}$. Then

$$(2.3) \quad h(x) \mid 1 + x^M, \text{ where } M := M(h) = 2^k \cdot \text{lcm}(2^{d_1} - 1, \dots, 2^{d_s} - 1).$$

Suppose $h \in \mathbb{F}_2[x]$ and $h(0) = 1$. The *period* of h is the smallest $T \geq 1$ so that $h(x) \mid 1 + x^T$; this definition does not assume that h is irreducible. The period of h can be much smaller than $M(h)$, however it is always a divisor of $M(h)$.

Lemma 2.2. *If h has period T , then $h(x) \mid 1 + x^V$ in $\mathbb{F}_2[x]$ if and only if $T \mid V$.*

Proof. We first note that $(1 + x^T) \mid (1 + x^{kT})$, proving one direction. For the other, suppose $h(x) \mid 1 + x^V$; then $V \geq T$. Write $V = kT + r$, where $0 \leq r \leq T - 1$. Then $h(x)$ also divides

$$(2.4) \quad x^r(1 + x^{kT}) + 1 + x^V = 1 + x^r,$$

which violates the minimality of T unless $r = 0$. \square

If $h \in \mathbb{F}_2[x]$ is irreducible, $\deg h = r$ and the period of h is $2^r - 1$, then h is called *primitive*. Primitive trinomials have attracted much recent interest, especially when $2^r - 1$ is a Mersenne prime (see [3]); Lemma 2.1 implies that all such irreducible h are primitive. In coding theory, h is called the *generator* polynomial and

$$(2.5) \quad q(x) = \frac{1 + x^T}{h(x)}$$

is called the *parity-check* polynomial.

Consider a rational function in $\mathbb{F}_2(x)$:

$$(2.6) \quad \frac{g(x)}{h(x)} = a(x) + \frac{r(x)}{h(x)},$$

where g, h, a, r are polynomials, and $\deg r < \deg h$. We make the additional assumption that $h(0) \neq 0$. Lemma 2.1 leads to an important relationship between rational functions and eventually periodicity.

Lemma 2.3. *Suppose $b(x) = \sum b_n x^n \in \mathbb{F}_2[[x]]$ with $b_0 = 1$. Then $b(x)$ is a rational function if and only if $\{n : b_n = 1\}$ is eventually periodic.*

Proof. First suppose there exists T, N so that $b_n = b_{n+T}$ for $n \geq N$. Then the coefficient of x^{n+T} in

$$(2.7) \quad (1 + x^T) \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

is $b_{n+T} + b_n = 0$ for $n \geq N$. Hence, $b(x)$ is the quotient of a polynomial of degree $< N$ and $1 + x^T$, and is thereby a rational function. Conversely, suppose $b = \frac{g}{h}$ is rational and is given by (2.6) with $h(0) = 1$. Then by Lemma 2.1, there exists $q(x) \in \mathbb{F}_2[x]$ and T so that

$$(2.8) \quad b(x) = a(x) + \frac{r(x)}{h(x)} = a(x) + \frac{r(x)q(x)}{1 + x^T},$$

hence $(1 + x^T)b(x)$ is a polynomial of degree $< N$ (say), so $b_n = b_{n+T}$ for $n \geq N$. \square

3. PROOFS

We start this section with two proofs of Theorem 1.1. The first one is somewhat longer, but yields a recurrence of independent interest.

As in (1.7), write

$$(3.1) \quad \begin{aligned} \mathcal{A} &= \{0 = a_0 < a_1 < \dots\} = \mathcal{A}_0 \cup \mathcal{A}_1; \\ \mathcal{A}_0 &= \{0 = 2b_0 < 2b_1 < \dots\}, \quad \mathcal{A}_1 = \{2c_1 + 1 < \dots\}. \end{aligned}$$

We will write $f_{\mathcal{A},2}(n)$ as $f(n)$ when there is no ambiguity. By (1.8), we have:

$$(3.2) \quad f(2n) = \sum_i f(n - b_i), \quad f(2n + 1) = \sum_j f(n - c_j).$$

Theorem 3.1. *For all $n \in \mathbb{Z}$, $n \neq 0$,*

$$(3.3) \quad \Theta(n) := \sum_k f(n - a_k) \equiv 0 \pmod{2}.$$

Proof. If $n < 0$, then $f(n) = 0$, so this is immediate; also $\Theta(0) = f(0) = 1$. Suppose $n > 0$. We distinguish two cases: $n = 2m$ and $n = 2m + 1$, and put (3.2) back into itself, diagonalizing the double sums below; for each fixed m , these sums are finite:

$$(3.4) \quad \begin{aligned} \Theta(2m) &= \sum_k f(2m - a_k) = \sum_i f(2m - 2b_i) + \sum_j f(2m - 2c_j - 1) \\ &= \sum_i \sum_u f(m - b_i - b_u) + \sum_j \sum_v f(m - c_j - 1 - c_v) = \\ &\quad \sum_i f(m - 2b_i) + 2 \sum_{i < u} f(m - b_i - b_u) \\ &\quad + \sum_j f(m - 2c_j - 1) + 2 \sum_{j < v} f(m - c_j - c_v - 1) \equiv \Theta(m) \pmod{2}. \end{aligned}$$

Similarly,

$$(3.5) \quad \begin{aligned} \Theta(2m + 1) &= \sum_k f(2m + 1 - a_k) = \sum_i f(2m + 1 - 2b_i) + \sum_j f(2m - 2c_j) \\ &= \sum_i \sum_j f(m - b_i - c_j) + \sum_j \sum_i f(m - c_j - b_i) = \\ &\quad 2 \sum_{i,j} f(m - b_i - c_j) \equiv 0 \pmod{2}. \end{aligned}$$

Since $\Theta(2m) \equiv \Theta(m)$ and $\Theta(2m + 1) \equiv 0$, $\Theta(m) \equiv 0$ for $m \geq 1$ by induction. \square

We now give two proofs of Theorem 1.1. The first uses Theorem 3.1 and the second uses the generating function (1.3).

First proof of Theorem 1.1. Write out the product in (1.9) and use Theorem 3.1.

$$(3.6) \quad F_{\mathcal{A},2}(x)\phi_{\mathcal{A}}(x) = \left(\sum_{n=0}^{\infty} f(n)x^n \right) \left(1 + \sum_{i \geq 1} x^{a_i} \right) = \sum_{n=0}^{\infty} \Theta(n)x^n \equiv 1.$$

□

Second proof of Theorem 1.1. By repeated use of (1.4) and (2.1),

$$(3.7) \quad \phi_{\mathcal{A}}(x)F_{\mathcal{A},2}^2(x) \equiv \phi_{\mathcal{A}}(x)F_{\mathcal{A},2}(x^2) = \phi_{\mathcal{A}}(x) \prod_{k=0}^{\infty} \phi_{\mathcal{A}}(x^{2^{k+1}}) = F_{\mathcal{A},2}(x).$$

□

The second proof generalizes immediately to primes $p > 2$ as a result of (2.1).

Theorem 3.2. *If $b = p$ is prime, then $F_{\mathcal{A},p}^{p-1}(x)\phi_{\mathcal{A}}(x) = 1 \in \mathbb{F}_p[x]$.*

Proof. As before, we have

$$(3.8) \quad \phi_{\mathcal{A}}(x)F_{\mathcal{A},p}^p(x) = \phi_{\mathcal{A}}(x)F_{\mathcal{A},p}(x^p) = \phi_{\mathcal{A}}(x) \prod_{k=0}^{\infty} \phi_{\mathcal{A}}(x^{p^{k+1}}) = F_{\mathcal{A},p}(x).$$

□

This result may fail if b is not prime. For example, if $\mathcal{A} = \{0, 1\}$ and $b = 4$, then $\phi_{\mathcal{A}}(x) = 1 + x$ and the coefficient of x^2 in $F_{\mathcal{A},4}^3(x)\phi_{\mathcal{A}}(x)$ is $6 \not\equiv 0 \pmod{4}$. Note also that Theorem 3.2 implies that $F_{\mathcal{A},p}(x) = \phi_{\mathcal{A}}^{-1/(p-1)}(x) \in \mathbb{F}_p[[x]]$.

Proof of Corollary 1.2(1). Suppose \mathcal{A} is finite and T is the period of $\phi_{\mathcal{A}}(x)$. Then by Theorem 1.1 and Lemma 2.1, we have in $\mathbb{F}_2[x]$

$$(3.9) \quad F_{\mathcal{A},2}(x) = \frac{1}{\phi_{\mathcal{A}}(x)} = \frac{q(x)}{1 + x^T},$$

where $(1 + x^T)F_{\mathcal{A},2}(x) = q(x) = 1 + \sum x^{b_k}$ and $\deg(q) < T$. Since the coefficient of x^{n+T} in q is $f(n+T) - f(n) = 0$, $(f(n) \pmod{2})$ is periodic with period T . □

Let $\mathcal{A}' = \{0 = b_0 < b_1 < \dots\}$ denote the (finite) set of exponents which occur in q in (3.9); $q(x) = \phi_{\mathcal{A}'}(x)$. It follows from Theorem 1.1 that

$$(3.10) \quad F_{\mathcal{A}',2}(x) = \frac{1}{\phi_{\mathcal{A}'}(x)} = \frac{1}{q(x)} = \frac{\phi_{\mathcal{A}}(x)}{1 + x^T}.$$

Equation (1.10) now follows from (3.9) and (3.10). One might hope that $(\mathcal{A}')' = \mathcal{A}$, but that will not be the case if \mathcal{A}' has a smaller period than \mathcal{A} . For example, if $\mathcal{A}_d = \{0, \dots, d-1\}$, then $\phi_{\mathcal{A}_d}(x)(1+x) = 1+x^d$, so for each d , $\mathcal{A}'_d = \{0, 1\}$. In terms of (1.10), $f_{\mathcal{A}_d,2}(n)$ is odd if and only if $n \equiv 0, 1 \pmod{d}$ (as proved in [8]) and $f_{\mathcal{A}'_d,2}(n)$ is odd if and only if $n \equiv 0, 1, \dots, d-1 \pmod{d}$. That is, $f_{\mathcal{A}'_d,2}(n)$ is odd for all $n \geq 0$, which is true, because it always equals 1.

Since $(f_{\mathcal{A},2}(n) \pmod{2})$ is periodic, it is natural to ask for the proportion of even and odd values. It follows immediately from (1.10) that the density of n for which $f_{\mathcal{A}}(n)$ is odd is equal to $|\mathcal{A}'|/T$. Computations with small examples lead to the conjecture that $|\mathcal{A}'| \leq \frac{T+1}{2}$. This conjecture is false. The smallest such example we have found is $\mathcal{A}_0 = \{0, 1, 5, 9, 10\}$. It turns out that the period of \mathcal{A}_0 is 33 and $|\mathcal{A}'_0| = 18 > \frac{33+1}{2}$. On the other hand, it is not hard to show that if $\phi_{\mathcal{A}}$ is primitive, then $|\mathcal{A}'| = \frac{T+1}{2}$. We hope to say more about this topic in a future publication.

Proof of Corollary 1.2(2). By Lemma 2.3, if \mathcal{A} is infinite, then $(f_{\mathcal{A},2}(n) \pmod{2})$ is eventually periodic if and only if $F_{\mathcal{A},2}(x)$ is a rational function, and by Theorem 1.1, this is so if and only if $\phi_{\mathcal{A}}(x)$ is a rational function. Suppose

$$(3.11) \quad \phi_{\mathcal{A}}(x) = a(x) + \frac{q(x)}{1+x^T} \in \mathbb{F}_2(x),$$

where $a, q \in \mathbb{F}_2[x]$, $\deg a < N$ and $\deg q < T$ and $q(x) = 1 + \sum_i x^{b_i}$. Then for $m > N$, $m \in \mathcal{A}$ if and only if x^m appears in $\phi_{\mathcal{A}}(x)$. By (3.11), this holds if and only if there exists $b_i \in \mathcal{A}'$ so that $N \equiv b_i \pmod{T}$. \square

We conclude this section with the proofs of Theorem 1.3(1) and (2).

Proof of Theorem 1.3(1). Let $f(n) := f_{\{0,1,2\},2}(n)$ and suppose $f(n+T) \equiv f(n) \pmod{d}$ for all sufficiently large n , where T is minimal. By (1.8),

$$(3.12) \quad f(2m) = f(m) + f(m-1); \quad f(2m+1) = f(m)$$

for all m . If $T = 2k$ is even, then for all sufficiently large m ,

$$(3.13) \quad f(2m+2k+1) \equiv f(2m+1) \pmod{d} \implies f(m+k) \equiv f(m) \pmod{d},$$

violating the minimality of T .

If $T = 2k+1$ is odd, then for all sufficiently large m ,

$$(3.14) \quad \begin{aligned} f(2m+2k+2) &\equiv f(2m+1) \pmod{d} \implies \\ f(m+k+1) + f(m+k) &\equiv f(m) \pmod{d}, \end{aligned}$$

and

$$(3.15) \quad \begin{aligned} f(2m+2k+3) &\equiv f(2m+2) \pmod{d} \implies \\ f(m+k+1) &\equiv f(m) + f(m+1) \pmod{d}. \end{aligned}$$

Together, these imply that for all sufficiently large m ,

$$(3.16) \quad f(m+k) \equiv -f(m+1) \pmod{d},$$

which implies that f has a period of $2k-2$. If $k > 1$, then $0 < 2k-2 < 2k+1$ gives a contradiction. If $k = 1$, then $T = 3$. We now show that $d = 2$. First, $f(2^r - 1) = f(2^{r-1} - 1)$ and so by induction, $f(2^r - 1) = f(1) = 1$. Thus, $f(2^r) = f(2^{r-1}) + f(2^{r-1} - 1) = f(2^{r-1}) + 1$ and so by induction, $f(2^r) = r + 1$, implying that $f(2^r + 1) = f(2^{r-1}) = r$ and $f(2^r + 2) = f(2^{r-1}) + f(2^{r-1} + 1) = r + r - 1$. Thus, d divides $f(2^r + 2) - f(2^r - 1) = 2r - 1 - 1$ for all sufficiently large r , hence $d = 2$. \square

Proof of Theorem 1.3(2). Suppose $\mathcal{A} = \{0, 1\}$ and $b \geq 3$. Then $f(n) := f_{\mathcal{A},b}(n) = 1$ if n is a sum of distinct powers of b , and 0 otherwise. Suppose that for $n > U$,

$$(3.17) \quad f(n+T) \equiv f(n) \pmod{d}.$$

and $d > 1$. Then, $f(m) \in \{0, 1\}$ implies that $f(n+T) = f(n)$. Now pick j so large that $b^j > T, U$ and suppose that f satisfies (3.17). Then $f(b^j) = 1$, hence $f(b^j + T) = 1$, and so $T = \sum_k b^{r_k}$ with distinct $r_k < j$. But then $f(b^j + 2T) = 1$ by periodicity, and so $b^j + 2\sum_k b^{r_k}$ must be also a sum of distinct powers of b , violating the uniqueness of the (standard) base- b representation. \square

4. EXAMPLES

Example 4.1. The periodicity of $f_{\mathcal{A},2}(n)$ was established in [8], motivated by the interpretation of the Stern sequence. In her dissertation, the second author [5] studied a variation on the Stern sequence defined by flipping the recurrence (1.11) to a two-parameter family of sequences. The periodicities discovered in [5] for $\mathcal{A} = \{0, 1, 3\}$ and $\mathcal{A} = \{0, 2, 3\}$ led the third author to suggest studying generalizations as the topic for the 2010 summer research project [1] of the first and fourth authors.

For $\alpha, \beta \in \mathbb{C}$, define $b_{\alpha,\beta}(n)$ by

$$(4.1) \quad \begin{aligned} b_{\alpha,\beta}(1) &= \alpha, & b_{\alpha,\beta}(2) &= \beta, \\ b_{\alpha,\beta}(2n) &= b_{\alpha,\beta}(n) + b_{\alpha,\beta}(n+1) \text{ for } n \geq 2, & b_{\alpha,\beta}(2n+1) &= b_{\alpha,\beta}(n) \text{ for } n \geq 1. \end{aligned}$$

(In order for the recurrence to be unambiguous, it can only apply starting at $n = 3$; the value of $b_{\alpha,\beta}(0)$ plays no role.) It is proved in [5] that $b_{0,1}(n+2) = f_{\{0,2,3\},2}(n)$ for $n \geq 0$. It was also proved there by an argument similar to the proof of Theorem 3.1 that $b_{0,1}(n) \equiv b_{0,1}(n+7) \pmod{2}$, and is odd when $n \equiv 0, 2, 3, 4 \pmod{7}$. This suggested looking at $f_{\{0,1,3\},2}(n)$, which is also periodic with period 7, and is odd when $n \equiv 0, 1, 2, 4 \pmod{7}$. The proofs of these facts are now straightforward in view of Theorem 1.1: we have in $\mathbb{F}_2(x)$:

$$(4.2) \quad \begin{aligned} F_{\{0,2,3\}}(x) &= \frac{1}{1+x^2+x^3} = \frac{(1+x+x^3)(1+x)}{1+x^7} = \frac{1+x^2+x^3+x^4}{1+x^7}; \\ F_{\{0,1,3\}}(x) &= \frac{1}{1+x+x^3} = \frac{(1+x^2+x^3)(1+x)}{1+x^7} = \frac{1+x+x^2+x^4}{1+x^7}. \end{aligned}$$

Thus, $\{0, 2, 3\}' = \{0, 2, 3, 4\}$ and $\{0, 1, 3\}' = \{0, 1, 2, 4\}$.

Example 4.2. For $r \geq 2$, let $\mathcal{A}_r = \{0, 1, 2, \dots, 2^r\}$ and $\mathcal{B}_r = \{0, 1, 3, \dots, 2^r - 1\}$ and let $g_r = \phi_{\mathcal{A}_r}$ and $h_r = \phi_{\mathcal{B}_r}$ for short. Then $g_r(x) = 1 + xh_r(x)$, so in $\mathbb{F}_2[x]$,

$$(4.3) \quad \begin{aligned} g_r(x)h_r(x) &= h_r(x) + xh_r^2(x) = h_r(x) + xh_r(x^2) = \\ &1 + \sum_{\ell=1}^r x^{2^\ell-1} + x + \sum_{\ell=1}^r x^{2^{\ell+1}-2+1} = 1 + x^{2^{r+1}-1}. \end{aligned}$$

This in itself does not establish that $\mathcal{A}_r, \mathcal{B}_r$ are complementary, or that they both have period $2^{r+1} - 1$. However, if they didn't, their period would have to be a proper factor of $2^{r+1} - 1$, which being odd, would be at most $\frac{1}{3}(2^{r+1} - 1) < 2^r - 1 < 2^r$, a contradiction. Thus g_r and h_r each have period $2^{r+1} - 1$. We may interpret this result combinatorially: $f_{\mathcal{A}_r, 2}(n)$ is the number of ways to write

$$(4.4) \quad n = \sum_{i=0}^{\infty} \epsilon_i 2^{i+k_i},$$

where $\epsilon_i \in \{0, 1\}$ and $0 \leq k_i \leq r$, and $f_{\mathcal{A}_r, 2}(n)$ is even, except when there exists $\ell < r$ so that $n \equiv 2^\ell - 1 \pmod{2^{r+1} - 1}$.

Example 4.3. We return to $\mathcal{A} = \{0, 1, 4, 9\}$; in $\mathbb{F}_2[x]$,

$$(4.5) \quad \phi_{\mathcal{A}}(x) = 1 + x + x^4 + x^9 = (1 + x)^4(1 + x + x^2)(1 + x^2 + x^3).$$

Note that $1 + x$ has period 1, $1 + x + x^2$ has period 3, and we have already seen that $1 + x + x^3$ has period 7. Since the maximum exponent in (4.5) is $\leq 2^2$, Lemma 2.1 implies that the period of \mathcal{A} divides $4 \cdot \text{lcm}(1, 3, 7) = 84$. Another calculation shows that $\phi_{\mathcal{A}}(x)$ does not divide $1 + x^{\frac{84}{p}}$ for $p = 2, 3, 7$, and so 84 is actually the period. A computation shows that $\mathcal{A}' = \{0, 1, 2, 3, \dots, 70, 75\}$ has 41 terms, as noted earlier. Thus $f_{\mathcal{A}}(n)$ is odd $\frac{41}{84}$ of the time and even $\frac{43}{84}$ of the time.

Example 4.4. Although Theorem 1.1 does not generalize to all \mathcal{A} if $(b, d) \neq (2, 2)$, there are a few exceptional cases. Problem B2 on the 1983 Putnam [6] in effect asked for a proof that for $\mathcal{A} = \{0, 1, 2, 3\}$,

$$(4.6) \quad f_{\mathcal{A}, 2}(n) = \left\lfloor \frac{n}{2} \right\rfloor + 1.$$

This can be seen directly from (1.4), since $\phi_{\mathcal{A}, 2}(x) = (1 + x)(1 + x^2) = \frac{1 - x^4}{1 - x}$, hence $F_{\mathcal{A}, 2}(x)$ telescopes to $\frac{1}{(1-x)(1-x^2)}$. It follows immediately that $f_{\mathcal{A}, 2}(n + 2d) = f_{\mathcal{A}, 2}(n) + d$, and hence $f_{\mathcal{A}, 2}$ is periodic mod d for each d , with period $2d$. A similar phenomenon occurs for $\mathcal{A}_b = \{0, 1, \dots, b^2 - 1\}$, so that $\phi_{\mathcal{A}_b, b}(x) = \frac{1 - x^{b^2}}{1 - x}$ and $F_{\mathcal{A}_b, b}(x) = \frac{1}{(1-x)(1-x^b)}$, implying that $f_{\mathcal{A}_b, b}(n) = \lfloor \frac{n}{b} \rfloor + 1$ and $f_{\mathcal{A}_b, b}(n + bd) = f_{\mathcal{A}_b, b}(n) + d$.

Example 4.5. Let $\mathcal{A} = 0 \cup (2\mathbb{N} + 1)$ (all non-zero digits in (1.1) are odd). Then

$$(4.7) \quad \phi_{\mathcal{A}}(x) = 1 + \sum_{i=0}^{\infty} x^{2i+1} = 1 + \frac{x}{1 - x^2} = \frac{1 + x - x^2}{1 - x^2}.$$

Working in $\mathbb{F}_2(x)$, we have

$$(4.8) \quad F_{\mathcal{A}, 2}(x) = \frac{1 - x^2}{1 + x - x^2} = \frac{(1 + x)^2}{1 + x + x^2} = 1 + \frac{x}{1 + x + x^2} = 1 + \frac{x + x^2}{1 + x^3}.$$

Thus, $f_{\mathcal{A}, 2}(n)$ is odd if and only if $n = 0$ or n is not a multiple of 3.

Example 4.6. Let $\mathcal{A}^{\{k\}} := \mathbb{N} \setminus \{k\}$. By Theorem 1.1,

$$(4.9) \quad \begin{aligned} \phi_{\mathcal{A}^{\{k\}}} &= \frac{1}{1+x} - x^k = \frac{1-x^k-x^{k+1}}{1+x} \implies F_{\mathcal{A}^{\{k\}}}(x) = \frac{1+x}{1+x^k+x^{k+1}} \\ &\implies F_{\mathcal{A}^{\{1\}}}(x) = \frac{1+x}{1+x+x^2} = \frac{(1+x)^2}{1+x^3} = \frac{1+x^2}{1+x^3}. \end{aligned}$$

Thus $f_{\mathbb{N} \setminus \{1\}, 2}(n)$ is odd precisely when $n \equiv 0, 2 \pmod{3}$. This may be contrasted with $f_{\{0,1,2\}, 2}(n)$, which is odd precisely when $n \equiv 0, 1 \pmod{3}$.
